#### SOLAR RADIATION.

Observations on solar radiation were made with a pair of maximum thermometers, one black and one bright bulbed, in vacuo, exposed horizontally on a post 4 feet high on the knoll southwest of the station. They were mounted side by side in a movable frame so that they could be brought into the house in stormy weather. These thermometers were exposed for a short time on November 13 and 14, 1882, just before the departure of the sun, but the latter was too near the horizon to produce any sensible effect. On the return of the sun, January 29, 1883, they were exposed every day not stormy from sunrise to sunset, the indices being set and read at sunrise and read again at sunset, till February 19, and about midnight, Washington time, until May 14th, when, the sun being continually above the horizon, they were set at local midnight and read at Washington midnight. This was continued till the closing of the station.

Statement showing the solar radiation at Uglaamie from February, 1883, to August, 1883.

[A pair of maximum thermometers, one black and one bright bulbed, exposed for solar radiation. Washington time. Correction to reduce to mean local time, —5 \* 17 \*\*.]

#### TERRESTRIAL RADIATION.

A minimum thermometer was exposed for terrestrial radiation from November 16, 1882, to the closing of the station, and read every day at Washington midnight. It was laid upon a board securely fixed upon the surface of the ground, and a box was provided with which it could be covered during snow storms, to prevent injury to the thermometer in digging it out of a snow-drift. Snow storms or drift of snow of course prevented observations with this thermometer.

On January 14, 1883, the Yale special minimum thermometer, No. 7 (carbon disulphide), was exposed beside this in its case, but was destroyed on January 25th by the Eskimo dogs, which gnawed off the end containing the bulb, attracted probably by the varnish on the case.

Statement showing the terrestrial radiation at Uglaamie from November, 1882, to March, 1883.

[Washington time. Correction to reduce to mean local time, - 8th 17th. Special minimum, CSs, No. 7, exposed for terrestrial radiation January 14, 1883; destroyed by Eskimo dogs January 25, 1883. Terrestrial minimum and air minimum read at 12 midnight, Washington time.

<sup>\*</sup>Column broken.

<sup>†</sup> Not exposed; drifting snow.

<sup>;</sup> Thermometer disturbed.

#### SEA-ICE TEMPERATURE.

On November 13, 1882, a wooden box, about 6 inches square on the bottom, with a sliding cover, was placed in an excavation about 4 inches deep made in the sea-ice about 50 yards from the shore. In this a spirit thermometer (No. 684) was set upright, and the bottom of the box filled with sea-water, which immediately froze, so as to inclose the bulb of the thermometer in ice.

A break in the ice near the shore occurred on the night of Nevember 20, and the ice moved away, carrying the thermometer with it. Spirit thermometer No. 713 was exposed in a similar box on December 19, 1882, and was kept in place till June 6, 1883, when the ice was beginning to melt on the surface. These thermometers were read every day about local noon.

The ice formed to the depth of  $5\frac{1}{14}$  feet, and while the temperature of the water immediately beneath it continued practically constant at about 29° F., the ice showed considerable variation. When the temperature of the air was low, the temperature of the ice was, as a rule, higher than that of the air. The reverse was true, as a rule, when the weather grew warmer.

#### TEMPERATURE OF THE SEA.

From November 11, 1881, till May 7, 1883, the temperature of the sea-water was observed once a day, from 12 m. to 2 p. m., local time, and hourly from May 7 to the end of the voyage home. It was taken at the surface and bottom in 17 feet of water, about 100 yards from the shore, through a hole in the ice in the winter, and by rowing out in a small boat when the water was open. The surface temperature only was taken from the vessel.

The temperature of the water in the various fresh and brackish lagoons was taken from time to time during the winter, and although ice was formed upwards of  $6_b^*$  feet thick, leaving scarcely any water underneath it, unfrozen mud was found at the bottom.

Statement showing the sea-ice temperature at Uglaamie from November, 1882, to June, 1883.

Observations taken at noon, local time; water temperature taken on bottom, 17 feet deep, one-eighth mile from shore.

May 2, temperature at "lead" of open water 2 miles from shore off station: surface, 29 .24 bottom, 78 feet, 29 .2.

#### TEMPERATURE OF THE EARTH.

A shaft was opened in the frozen earth for the observation of earth temperatures December 8, 1881, and continued down to a depth of 37 feet 6 inches. A thermometer protected by a wooden case was buried at the bottom of the shaft by the workman every night and read on beginning work the next morning. From May 28, 1882, to April 23, 1883, a thermometer was kept suspended in the meat cellar at a depth of 13 feet below the surface and read once a day. From April 23, 1883, to the closing of the station the thermometer was let down by a cord to the bottom of the shaft and drawn up and read once a day. At this level the temperature remained constant at + 12° F.

Temperature of the earth at Uglaamie, Alaska, from December 8, 1881, to February 17, 1883.

Five feet of snow was removed from over the shaft. The thermometer was buried in bottom, same as on December 17, when the temperature was taken.

From this date until the closing of the station the temperature was observed daily at this depth, and found to be constant at 12°. If a temperature was observed daily at this depth, and found to be constant at 12°.

#### METEOROLOGY OF MEADE RIVER RECONNAISSANCE.

These observations were taken by Lieut. P. H. Ray, and Mr. A. C. Dark, during the sledge journey towards the headwaters of Meade River, from March 28 to April 7, 1883, inclusive. The instruments used were one aneroid barometer, and two ordinary spirit-thermometers, protected by tubular wooden cases open at the bottom, and exposed by hanging them to the mast of the sled, four feet from the ground. The velocity of the wind was estimated, and its direction indicated by a fly of bunting at the masthead.

eember 8, a wooden beginning uspended April 23, om of the constant

itinued.

Meteorological record of the reconnaissance to Meade River, Alaska.

# METEOROLOGY OF THE VOYAGE FROM POINT BARROW TO SAN FRANCISCO.

These observations are the direct continuation of the regular meteorological work of the station, and were taken as above described.

Meteorological record of the coyage of the schooner Leo from Point Barrow, Alaska, to San Francisco, California.

AUGUST 28, 1880.

[Washington time. Correction to reduce to local time, +5 hours 17 minutes. Italic x significs slow : x signifies rapid. Schooner abreast of station, Uglaamlo, Alaska, latitude 719 17 [N., longitude 1509 23] W.]

10.30 a.m. small, incomplete rainbow. 1 Light shower of rain between observations. 14.35 a.m. passed the "Heeds" into the Harbor of San Francisco.

#### AURORA.

The aurora was observed hourly during the whole period when there was sufficient darkness to allow it to be visible, and any extraordinary appearances observed between the hours were also noted.

The bearings given all refer to the true meridian, and as well as the altitudes are all estimated, as the aurora was never quiet enough for instrumental observation.

The brightness of the aurora was estimated on a scale of 0 to 4.

AURORAL RECORD, OOGLAAMIE, ALASKA, 1881, 1882, 1883.

Time of beginning and time of ending-Washington time.

October 17, 1881, 1.57 a. m. to 3.35 a. m.—From a point 30° W. of N. through Ursa Major and the Pleiades to a point about 15° E. of S. It was requilibrate arch of white light showing very little tremulous or lateral motion and only a few mercy-decembers were observed. As a whole it had a motion to the S. and moved nearly 45° past the zenifal pefore it was obscured.

October 22, 1881, 2.40 a. m. to 6.30 a. m.—F. ou the NNW. to the SE., passing through Ursa Major, the Pleiades and Hyades. Very brill not white light without any changes of color. Very bright toward its southern end. Several arcnes operared in succession. Very little lateral motion.

October 27, 1881, 7 a. m. to 7 a. m.—Observed through breaks in the clouds. It was apparently brilliant, but the weather was too cloudy to allow it to be observed.

October 27 and 28, 1881, 10.30 p. m. to a m.—From a point 5° W. of N. to the SE. Not remarkably brilliant, but displayed a good deal of tremulous motion, and sometimes assumed the curtain form. At first it was white, but changed to sulphur yellow. Position constantly changing, but the change confined to the higher part of the arch, the ends retaining a comparatively fixed position. Time of ending is the time last seen.

October 30, 1881, 7 a. m. to 10 a. m.—General position as usual, and not stationary for any time. A bright arch of the curtain character possessed a good deal of motion, both of vibration and translation. A few streamers at 7.30 a. m.

November 3, 1881, 2.30 a. m. to 5 a. m.—NW. to SE., passing through Ursa Major and the Pleiades. An arch of irregular form and pale color. Cloudiness prevented much observation. But little motion observed.

November 6, 1881, 12.15 a. m. to 7.10 a. m.—From NNW, to nearly SE. Position constantly changing. Not very brilliant, but dimmed by the superior brilliance of the moon. There were intervals of cessation amounting at times to an hour and more, when it became imperceptible. At 7 a. m. it flashed into great brilliance for a short time. It then extended from the horizon NNW, through Cygnus to Cassiopeia, where it curved back toward the NW. It was then full of quivering vibratory motion, the motion being mainly lateral or back and forward from E. to W.

November 7, 1881, 6 a. m. to 8.10 a. m.—General direction from NW. to SE.; position constantly changing. Three bands sometimes uniting and forming one, and sometimes two arches. Very brilliant at times and a great deal of vibratory motion observed.

November 11, 1881, 9 a. m. to 10 a. m.— N. to NE. Faint bands changing rapidly and vertical to the horizon. There were several patches of flocculent light, sometimes approaching the curtain form, but always very faint.

November 12, 1881, 4.50 a. m. to 8.30 a. m.—When first seen it was low down near the northern horizon extending from NNW, to SE., and rising slowly. At 7 a. m. it extended through Ursa Major and Leo down to the SE. At 8 a. m. nothing remained but a short curtain directly below Cygnus. 'faint and irregular arch with a slow upward motion. Very few traces of color and very little quivering or lateral motion. Rendered fainter by the moonlight. Weather clear.

November 12 and 13, 1881, 10.50 p. m. to 10.30 a. m.—North, low down. At 12 m. a very faint arch with its center in Gemini. At 7 a. m. a faint light extending from Orion to the moon. A streamer in the E. at 9 a. m.; still visible at 10 a. m. Faint rays perpendicular to the horizon, sometimes scarcely perceptible, but possessing a quick flashing motion as if it were the reflection

H. Ex. 44---46

of lights below the horizon. When the arch appeared it had no apparent motion and only last-at a short time; the light in the S. at at 7 a.m. resembled a band of faintly illuminated cirrus cloud, November 15, 1881, 3 a. m. to 3.15 a. m.—Position not observed. Seen through breaks in the clouds.

November 16, 1881, 6.45 a.m. to 10,30 a.m.—NW, to SE.; position continually changing. First seen at 6.45 a.m., when the clouds rolled off. At 8 a.m. an irregular curtained arch ran from the NW, horizon, passing 8, of the Pleiades through Orion and down to the moon. Below this to the 8, was a complete arch clevated about 15° above the horizon with a well defined dark segment below it. Patches of nebulous light were, at the same time, visible in different parts of the 8ky to the N, and NE. At 9 a.m. several detached segments of curtains were scattered over the zenith and N, and NE, sky, while a broad and pale band extended round the southern sky from the NW, to the SE, forming a semicircle elevated about 10° above the horizon with the "dark segment" below it. At 10 a.m. all that remained was a pale narrow band passing through the zenith, and at 10.39 all had faded away.

November 16, 1881, 9:30 p. m. to 11.55 p. m.—From NNW, to SE, constantly changing both in position and appearance. Arch developed rapidly into a broad curtain with a number of streamers at its northern end. It rose rapidly, passed the zenith and soon faded away, and was succeeded by another very brilliant one, of intense sulphur-yellow color, running through the zenith from NW, to SE. There was a quick quivering motion, curtains formed and faded, and faint rays shot upward in the well-known form of flames arising from burning alcohol; these arches followed each other in quick succession and seemed mostly to be propagated from the SE, to the NW, Disappeared at 11.35 p. m.

Vorember 17, 1881, 7 a. m. to 11.40 a. m.—NW. to SSE. A low arch passing through the belt of Orion, brightness 2. Another narrow band (brightness 3) reached from NW. horizon to the Hyades, Very little change was exhibited except that the light grow gradually paler, and at 9 a. m. had resolved itself into a number of nebulous patches scattered over the southern half of the sky, but at the same time a bright curtain appeared near the northern horizon. All faded and became more diffused, and finally disappeared at 11.40 a. m.

November 18, 1881, 1 a. m. to 1 p. m.— Large auroral streamers rising from near the northern horizon almost to the zenith, first seen at 1 a. m., and had disappeared at 2 a. m. At 7.20 a. m. it reappeared, and several bands or irregular arches appeared, passing through the zenith from NW. to 8E., but being, to a great extent, obscured by clouds, their position and peculiarities could not well be determined. The arches had changed at 9 a. m. to a broad band of very pale diffused light to the southward running through Orion. Seen at intervals, though very indistinct, until 1 p. m., when it entirely disappeared.

November 19, 1881, 3.40 a. m. to 3.30 a. m.—A pale narrow band appeared in the zenith running from from NW, to SE.—Disappeared at 3.30 a. m.

November 19, 1881, and 20, 1881, 8 p. m. to 10.40 a. m.—This aurora was a very extensive one and assumed a very great variety of shapes and positions. It was at no time very brilliant as a whole, though some of the curtains were quite bright. There were but few traces of color other than bright sulphur yellow and white. There seemed two foci from which the rays, bands, and arches seemed to spring, one in the NNW, and the other in the SE. From these points the arches were mostly propagated in direction of their length, not simultaneously but very irregularly. The development of the arches was always rapid, and, once they were formed, their motion upward to the zenith and to the southward, though not very perceptible at any particular instant, was also very rapid. At 7 a. m. the greater part of the sky was more or less illuminated: bands, curtains, and patches of pale nebulous light were scattered over it in great confusion. After this it began to fade, and disappeared at 10.10 a. m.

November 21, 1881, 9 a. m. to 19:20 a. m.—Indistinct and dim; seen through the clouds, so that peculiarities, if any, could not be observed.

Norember 21 and 22, 1881, 12 mid-day to 10.40 a.m.—Had some short intervals of intermission and periods of comparative brilliancy. The light was very pale and diffusive, the bands mostly broad and ill-defined. At 7 a.m. reached its greatest brilliance, when a bright irregular arch was formed, narrow at the ends and very broad at the top. The broad part consisted of a number of bands,

nly lasted rus cloud, iks in the

ls, so that

ssion and tly broad s formed, of bands, sometimes reaching the number of six, but mostly fewer. When at their broadest they extended from Regulus to the head of Orion. All the arches that appeared had the usual motion to the southward. There was a good deal of vibratory motion, but the vibrations being extremely short they were scarcely perceptible. Most of the arches were propagated laterally from the SE. Finally it broke up into numerous rays and nebulous patches scattered over the sky and disappeared.

Narember 23, 1881, 1 a. m. to 10,20 a. m.—Commenced as faint diffused light near the northern horizon, which soon brightened and extended to the eastward, so as to form a bright curtained farch which at 2 a. m. extended through Ursa Major, through Gemini, and a little above Orion, with both its ends sharply curved toward the N.—From its upward side rose numerous slender quivering rays of almost imperceptible light, which sometimes separated from the parent arch and amited laterally at their bases, forming a second but less brilliant arch above the old one. Occasional streamers appeared at its north end.—I may here remark that the sharp curvature of the ends of arches toward the N, is a general feature up to the present. At 7 a. m. reduced to a broad extending a few degrees along the northern horizon with steady light and brightness 3, Very faint arches in the S.

Eight a. m. low arch running from SSE, to SW., E. end brilliant, highest point between Orion and the Hyades: at 9 this arch had developed into a broad fan-shaped sheaf of pale streamers using nearly to the zenith. After this it gradually faded and disappeared at 10.20 a. m.

November 23 and 24, 1881, 9.30 p. m., 12 noon.—Faint streaks and partly developed rays in the SE, at 9.30 p. m. Soon afterwards developed into several broad bands of very irregular shape extending from SE, to NW, through Ursa Major. Very bright spiral whorls in the SE, at 11 p. m. while a faint band crossed to the NW.—At 12 p. m. top of arch was in Cygnus pale in the SE, but bright in the NW, with an occasional streamer.—After this slowly faded, and all that remained until 6 a. m. was a band of very pale diffused light lying along the S, and SW, horizon.

At 7 a. m. a pale semicircular arch extended around the horizon with an elevation of about 15 from a point right under Regulus through the head of Orion, and ended in the NW. In the W., when brightest, a number of pale converging rays shot up occasionally towards the zenith, which soon afterwards rose and formed an imperfect corona with converging point exactly in the zenith. There was a great display of motion—very rapid—up and down and lateral, but with nothing approaching regularity. Merry dancers, whorls, and convolutions followed each other in quick succession. The general motion was from S. to N., the opposite of what it usually is. After it passed the zenith it became very bright in the NW. so that the illumination cast therefrom on the snow was distinctly visible; occasional dark rays at this time shot across it upwards towards the zenith. They appeared very dark, and seemed like shadows of some opaque bodies thrown across the surrounding brightness. At 9 a. m. it was considerably faded, and all that remained was the usual faint band lying near the southern horizon running from SE, to NW. At about 11 a. m. it brightened somewhat again and a few rays again appeared in the NW, and extended nearly to the zenith. Disappeared at 12 m.

November 25, 1881, 5 a, m, to 9 a, m.—Faint patches appearing at intervals at different parts of the sky, principally in the E.; at 8 a, m, had developed into a broad wavy line running from SE, horizon through zenith to the NW., its brightest point being in the SE. At 8 a, m, a small arch from SE, to N, about 15° above the horizon, and another broken irregular arch from the same point to the NW, but very faint; still seen through breaks in the clouds at 9 a, m., but immediately afterwards obscured.

November 26, 1881, 2.20 a, m, to 3.30 a, m, +Occasional glimpses of auroral bands through the clouds to the SE, during this time.

November 27, 1881, 1 a. m. to 9 a. m.—Probably brilliant, but the clouds prevented it being satisfactorily seen. At 2 a. m. the light appeared to form a circle round the zenith, a corona being probably formed. An arch of irregular shape ran from N. to SE, at an elevation of about 15° above the northern horizon at 7 a. m., brightest at the N. end, with occasional streamers. After this it became much dimmer, but did not disappear until it was obscured by clouds about 9 a. m.

November 28, 1881, 2 a. m. to 1 p. m.—When first observed it appeared as two low broken arches running from the SE, to a point NNW. At the same time the sky was covered with patches

of nebulous light resembling cirro-cumulus cloud. Changed rapidly, and was succeeded by a brilliant convoluted arch running up through Orion's 6-belt," through Taurus, and through Cassiopeia, which was in the zenith towards the NW. Faint and irregular until 7 a. m., when there was another burst of brilliancy. A brilliant scrpentine arch extended from the NNW, through Ursa Major to the SE. It exhibited none of the usual quiescence, but was rapidly and intensely in motion with streamers shooting apwards and converging towards a point in Auriga. There was no predominant direction of motion, and the general characters changed with great rapidity. The sky near the zenith was filled with bands, patches, and segments of arches, but all was changing every minute. The amount of light was 2, but no traces of color appeared other than white and pale sulphur yellow. After this there was no further display. The light became diffused and difficult to locate, with isolated patches appearing at intervals in different parts of the sky until it finally faded about 1 p. m.

November 28 and 29, 1881, 11.50 p. m to 6 a. m .- First observed as a faint band starting exactly at Arcturus and running a little below Ursa Major until lost in the clouds near Gomini. This was rapidly succeeded by other bands and patches in various parts of the sky until about 1.50 a. m, of the 29th, when a magnificent burst of energy occurred. Over every part of the sky uncovered by clouds masses of light of every shape and form flashed out all in a condition of intense vibration. There seemed to be three foci of activity, one E., one S., and one W. (magnetic), each about 20° above the horizon. The changes in character were extremely rapid, so that it was impossible to get a mental image of the whole phenomena at any particular instant of time owing to this fact: the variety and multiplicity of features being such that the mind could not grasp them all at once. A brilliant but irregularly formed corona appeared with its converging point in Cassiopeia, which was then in the zenith, and flashed and gyrated, changing its character and shape every instant. The colors displayed were various and very intense-orange, green, pink, rose, yellow, and crimson: green and rose predominated. Magnet at this time was deflected 49 17 to the west of magnetic meridian. The display lasted about twenty minutes, after which it gradually faded and assumed the usual diffused and indistinct form. The increasing cloudiness prevented its being clearly observed afterwards, but traces were visible until 6 a.m.

November 30, 1881, 4.30 a. m. to 7.25 a. m.—Patches of nebulous light, incipient arches, and occasional pale rays slowly developed in various parts of the sky, all more or less diffused, but constantly changing in character. A pale wavy arch at 7 a. m. ran from the NW, through Cygnus to Arcturus, where it bent off to the S. until lost in the clouds at the feet of Orion. Sky obscured after 7 a. m.

December 1, 1881, 1,50 a.m. to 10 a.m.—Faint band appeared extending from a point almost due N., passing through Taurus and ending in Orion; narrow and moving slowly to the southward. Patches and bands and much diffused light succeeded, but assumed no very definite forms; obscured by clouds about 5.30 a.m.; still visible, though faint, until 10 a.m.

December 5 and 6, 1881, 11 p. m. to 2 a. m.—First observed as a faint band running from E. to SSW., with an altitude of 20°. Remained faint, and faded away occasionally, but very difficult to observe from the haziness of the sky. At 12 m. several bands appeared to the northward, passing through Ursa Major. Not seen after 2 a. m. of the 6th, but as the magnetic needles were constantly disturbed for several hours afterwards, it probably still continued, though obscured by clouds.

December 7, 1881, 8 a.m.—Small patches of curtain aurora in NW. at 8 a.m., with an altitude of 10°, sending up one long streamer: changing rapidly.

December 8, 1881, 12.30 a. m. to 12 midday.—This was one of the most magnificent displays that has yet occurred here. First appearance was in the S. and SE., and for several hours nothing appeared but a few pale arches and bands which had no remarkable feature worthy of notice except the rapidity with which they changed their position and character. They appeared faded, and reappeared in various parts of the sky so quickly that it was very difficult to localize them. At 2.40 a. m. a narrow greenish-yellow arch with a beautiful rosy fringe developed in the SSE and in a few minutes extended through Taurus, Cassiopeia, and Cygnus down to the N., and for about ten minutes displayed some extremely beautiful tints, especially along its northern half; it seemed to be composed of an infinite number of short rays in a condition of intense vibration, the

rs nothing notice exred faded, dize them. the SSE. \(\). and for \(\)n half; it ration, the motion being principally in direction of its length, while flashes of the most vivid coloring beamed out in most bewildering variety. At the same time numerous rays and patches of quivering light appeared in various parts of the sky in quick succession, dancing and gyrating to and fro swift as the lightning's flash. While the northern half of the arch remained thus brilliant, the southern half faded away. A few minutes afterwards a patch of rosy greenish light appeared in the middle of Orion and in a minute or two developed into numerous sheafs of rays with the greatest variety and intensity of motion and displaying the most brilliant colors as they rose and converged to a point close to the star Algol, forming an imperfect but most brilliant corona, which swayed and swirled and eddied round our zenith with a kaleidoscopic rangnificence utterly indescribable; the changes of tint, aspect, and position were so rapid and numerous that the eye strove to following their bewildering confusion in vain. The general motion was to the N., though a brilliant curtain was at the same time moving towards the zenith from the N. The brilliance of the moon seemed to have little effect on the intensity of the colors which appeared. The colors were very numerous, orange, yellow, rose, ruby-red, peach-blossom, emerald-green, and numerous intermediate tints changed and interchanged in beautiful confusion; the whole phenomena of waving wreaths, flickering fumes, rays, curtains, fringes, bands, and flashing colors, the strange confusion of light and motion, presented a picture of which words can convey a very poor idea. The whole display lasted about 30 minutes. There was also intense magnetic disturbance during this time, the needles being almost unmanageable. A peculiarity of this Aurora was its lowness in the atmosphere, several patches of cloud apparently not very clevated appearing far above it. Did not entirely disappear until about 12 midday. The apparent elevation of the cloud may have been caused by an optical illusion.

December 8 and 9, 1881, 10,50 p. m. to 10 a. m.—First appeared as a patch of nebulous light immediately below Ursa Major; other patches soon afterwards appeared, and several partially developed arches were observed up to midnight, when it brightened a little and several broad diffused bands were found passing through the zenith. Quivering rays appeared to the SE in Orion, and a partly formed corona in the zenith at 1 a. m.—After this to 10 a. in. occasional bands, patches, and rays of light appeared in various parts of the sky, and several times a complete arch was formed, but mostly pale and ill-defined. The magnetic needles were disturbed to a considerable extent about 8 a. m.

December 10, 1881, 10:30 p. m. to 12 m.—Faint detached rays appeared in various parts of the northern quarter of the sky, and a few converged towards the zenith from Ursa Major. Soon afterwards they faded considerably, and for intervals of half an hour at a time were entirely invisible.

December 11, 1881, 5 a. m. to 8 a. m.—Faint and irregular in shape, no variety of color, and but little motion other than the general motion of translation.

December 11, 1881, 11 p. m. to 11.15 p. m.—Straight auroral bands converging towards the zenith, all faint and pale, lasted about 20 minutes.

December 12, 1881, 2 a. m. to 10.50 a. m.—Two narrow bands (brightness 2) running from the north point to the SE. For the next four hours the sky was clouded, but at 7 a. m. a pale curtained band low down in the north under Cygnus with a few rays above it; this rose and expanded into numerous others, which covered the sky for about 20° on each side of the zenith, running from XW. to SE. There was very little motion at this time, but the magnetic needles were a good deal disturbed. At 9 a. m. there was a very irregular curtained arch in the zenith which constantly and rapidly changed both its position and character, the magnets being still disturbed. From 9.20 to 10.30 a. m. the aurora was invisible, but at 10.30 it reappeared in the shape of several bands and patches of floculent light in various parts of the sky and lasted 20 minutes, when it finally disappeared.

December 12 and 13, 4881, 9 p. m. to 10.30 a. m.—First seen at 9 p. m. as a broad pale arch of lambent luminiferous vapor running from N. to SE, with its center in Geraini. From this position it did not materially change until nearly 1 a. m. of the 13th. The dark segment was very strongly marked below it. This is the first aurora of this kind I have seen since our arrival; it is also the first that has remained for so long a period stationary—nearly four hours. About 1 a. m. it began moving upwards and augmented greatly in brightness, and in a few minutes developed

into an extremely brilliant band of yellowish white light rising from the horizon due N., making a great sweeping curve upwards, and extending through Cygnus to the zenith, Taurus, and down into Orion. There was much quiet movement, the vibrations being very short, mostly in direction of its length, but no variety of coloring. The pale hazy arch and dark segment reformed underneath, and hang for some time longer in the N. and NE. The bright arch above, however, soon moved to the southward, and a very brilliant series of broken curtains and convolutions appeared in Orion, but all soon faded considerably, and nothing appeared except numerous disconnected bands and patches of diffused and flocculent light until about 4.30 a. m., when it disappeared for nearly an hour. About 6 a. m. there was another brilliant burst in the N. moving very rapidly towards the horizon. Up to this time the magnets showed very little disturbance, but immediately on this display the disturbance became very great, the unifilar magnet being deflected out of the field to the W. so far that the azimuth circle had to be removed 2° 10' to bring it back so as to point the telescope on its axis. After 6 a. m. there were occasional rays and bands in various parts of the sky, but mostly pale and indistinct. All disappeared about 10.30 a. m.

December 14, 1881, 1 a. m. to 1 p. m.—First seen very indistinct near the SE, point of horizon, and afterwards only at intervals glimpses were had of it through the clouds, and was last seen as a narrow band of white light extending from NW, to SE, with its highest point in Ursa Mino. A

1 p. m.

December 14 and 15, 1881, JO p. m. to 2.30 p. m.—Faint traces in NE., where it remained as a series of irregular patches and partly arches, disappearing and reappearing from time to time up to about 2 a. m. of the 15th, when it became more extensive but still retained its diffused and irregular character. At 1 a. m. the magnets were much disturbed, though the display at the time was very faint; the weather being very hazy however at the time, it was difficult to determine its extent. Occasional bands formed and moved southward up to 12 midday, when several bands appeared and remained for a short time, but displayed no remarkable features. Disappeared about 2,30 p. m.

Pecember 15, 1881, 14 p. m, to 11 a. m. December 16.—Pale arch in NE, with its highest point in Cominj, but as the clouds soon increased rapidly its after position could not be determined, though occasional traces were observed through breaks. At 9 a. m., 16th, a broad pale band was visible through the clouds. It was not seen afterwards, but at 11 a. m. the magnets were greatly disturbed: the unifilar needle being so strongly deflected to the eastward that it was necessary to move the azimuth circle 3° 4′ so as to enable observer to point on axis. It remained in this con-

dition for nearly three hours.

December 16 and 17, 1881, 11 p. m. to 10,30 a. m.—Faint traces of auroral light low down in the NE.; at 12 midnight a still arch, broad, pale, and with the dark segment strongly marked below it, extended from the center of Boötes through Gemini down to the head of Orion. Very little motion was perceptible, and soon afterwards it disappeared, but seen reappeared again as a few straggling rays in Boötes, which continued to fade and flicker for a time and then faded away for a short interval, and so it fluctuated until about 6 a. m. of the 17th, when it suddenly became more brilliant. A brilliant series of bands and arches extended across the sky from NW. to 8E., passing through and on both sides of the zenith with a general southward motion. There was much, but not to a remarkable degree, internal vibratory motion. The unifilar magnet was deflected so strongly to the westward that the azimuth circle had to be moved 7° 12′ to bring it into the field. Numerous bands and arches, though not very brilliant, succeeded each other rapidly until about 8 a. m., when the phenomena became less distinct, and about 10.30 a. m. all had faded. The magnets remained in a disturbed condition until 8 a. m.

December 17 and 18, 1881, 11 p. m. to 1 p. m.—Pale nebulous patches appeared low down in the N. and NE, and a scarcely perceptible arch accompanied by a few slowly waving rays formed about 12 m. Afterwards patches appeared and disappeared at intervals, and occasional arches were formed, principally low in the NE. About 6.30 it began to brighten, and a rather bright arch passed down to the southward and faded away into a band of nebulous haze. After a few minutes' quiescence a brilliant patch appeared in the SE, a drapidly developed into an irregular custined arch which shot up numerous slender rays, and exhibited very intense activity. In a few minutes it had risen to the zenith, where a brilliant but imperfect corona was formed, which whirled

, making a and down ly in direcformed unvever, soon 8 appeared second etcl opeared for ery rapidly mucdiately out of the ack so as to

lown in the ed below it, ittle motion straggling for a short 2 more briller, passing connect, but effected so to the field, itil about 8 ie magnets

own in the med about rches were right arch a few minegular cur-. In a few ich whirled round and quivered and vibrated for a infinite or two with intense rapidity and then slowly moved to the northward, its coronal character changing into the irregular curtain form. There were some beautiful flashes of rosy red and deep green, but in general the color was an intensely brilliant yellowish white, and the light emitted was such as to render objects distinctly visible half a mile away. The magnets were disturbed, but not extremely. At 8 a. m. the greater portion of the sky seemed covered by a faintly luminous haze, and a very pale circle of diffused light extended all around the sky at an elevation of a few degrees above the horizon. After this only occasional streaks and patches appeared until about 1 p. m., when it disappeared.

December 18 and 49, 1881, 10.50 p. m. to 1.30 p. m.—A very faint arch formed in the NE., low down, which rose slowly with a few flickering rays shooting from its upward side, and at 12 m. its highest point just touched Cor Caroli in Canes Venatici. After this there was but little display other than a few straggling patches and rays scattered irregularly over the sky until about 8 a. m., when the brightness increased considerably and streamers appeared in various parts of the sky. Several narrow bands or arches rose from the N. and NE., broke up into irregular curtains, and inally passed down to the south, when they faded away into a kind of faintly luminous haze. The magnetic needles were deflected to the W.—An intermittent period again intervened until about 10 a.m., when another period of brilliancy occurred. Several bright curtains and streamers appeared in the S. and W. but did not exhibit much apparent motion. The magnets were again deflected, this time to the E.—A fer this no noticeable features appeared, and at 1.30 p. m. a few pale bands were visible in the zenith, but they soon disappeared before the brightening twilight.

December 19 and 20, 1881, 11 p. m. to 11 a. m.—Auroral light pale and diffused and appearing in the NE, as usual, but rather unusually stretching thence as a broad diffused band towards the W. At 11.30 this band faded away into a kind of luminous haze, which covered the greater part of the sky, and across this, stretching from Boötes down to the  $\mathrm{SW}_\alpha$  two parallel black bands appeared, which slowly rose towards the zenith, still retaining the same shape and relative positions and looking exactly like a jet-black aurora. They possessed all the characteristics of ordinary auroral bands except the color, and occasionally rays of shadow, if I may use the expression, streamed from their upper side, much the same as rays of light ordinarily do from auroral arches, The cause of this phenomenon seemed to be that two long rents appeared in the luminous haze and took and maintained for a considerable time the form of long bands stretching across the sky. They were certainly not streaks of cloud, for the stars shone brighter through them than in any part of the neighboring sky; their motion was not that of cloud, and their black color was given by confrast with the surrounding luminous haze. After passing the zenith they disappeared, but afterwards nothing appeared for several hours other than a few nebulous patches here and there, and the faintly luminous haze, which still remained unchanged as long as it could be observed, observation being rendered difficult by the increasing cloudiness. From 8 to 10 a.m. several bands appeared through the clouds in and near the zenith, and during that time the magnets were very much disturbed. Last traces observed at 11 a. m.

December 20 and 21, 1881, 14 p. m. to 10.30 a. m.—Faint nebulous masses of faint light low down in the NE., which soon expanded into a narrow still arch running from Arcturus through Canes Venatici and down until lost in the haze in the SE.—It rose very slowly, and as it approached the zenith divided into two, and afterwards into several, which passed towards the S., where they faded into a nebulous-haze and at 1.15 of the 21st nearly all the visible sky was covered with bands, patches, and imperfect arches, the general direction of which was from NW. to SE.—This condition of things remained until about 10 a. m., when there was a brilliant burst of sbort duration, consisting chiefly of vertical rays in extremely rapid motion, and converging towards the zenith where a brilliant but imperfect corona was formed, lasting for a few minutes.—A broad waving band moved up rapidly from the N. and collected into a mass at the zenith, and passed as rapidly to the SE.—The brightness was fully 4, and the colors principally white and yellow with tinges of green and rose on the edges.—Magnets much disturbed.—Unifilar deflected towards the east.—In about twenty minutes the display was over, and all that remained were numerous patches of light all round the horizon, which soon also disappeared.

December 21 and 22, 1881, 10 p. m. to 1 p. m.—As has been usual for some time back in the commencement of auroras, a few flocculent patches of hazy light appeared low down in the NE., which

blowly changed from time to time; those first appearing soon fading away and giving place to others of similar character until about 11.30, when they assumed the form of a regular arch, quiet and narrow, and extending from N. to SE, with an altitude of about 20 degrees. It rose very slowly and showed varying degrees of brightness, but was generally pale. At 3 a. m. of the 22d its center was in Ursa Major, and between 6 and 7 a. m. its center was in Auriga. After it passed the zenith it imperceptibly faded into a diffused luminous haze, which covered the greater part of the visible sky. Sections of half-formed curtains and arches appeared from time to time, and afterwards a very bright one formed in the E about 11 a. m. Traces of it were still visible at 1 p. m.

December 22 and 23, 1881, 11.30 p. m. to 2.15 p. m.—Faintly luminous haze appeared in the NE, at 11.30, but soon afterward disappeared in the haze which covered the sky. About 2 a. m., 23d, it reappeared in nearly the same position and apparently shining through the haze. After this it became brighter, showed more motion, and developed more rapidly. Faint arch succeeded faint arch, and bands and curtains flourished and faded too numerously and too irregularly to particularize, until about 4 a. m., when an imperfect corona was formed with its culminating point almost in the zenith. There was considerable variety of colors, yellow, pink, red, and white, the total light emitted being probably equal to that of a full moon, but as the emitting surface covered the greater part of the sky the light was much more diffused than moonlight. This period of intensity continued until about 5.30 a. m., when the bands and arches gave place to a diffused light spreading over the greater part of the visible sky. There was great magnetic disturbance during the period of maximum displays. The untillar magnet was deflected to the E. so as to necessitate the movement of the azimuth circle through 4° 10′, while the dip of the weighted dip needle increased 2° 15′. Last traces were observed at 2.15 p. m.

December 23 and 24, 1881, 8.30 p. m. to 2.15 p. m.—At 8.30 p. m. a faint pinkish ray rose from the SE, and extended upwards almost to the zenith, but lasted only a few minutes. Luminous patches soon afterward appeared in the NE., and a narrow quiet arch soon was formed, which remained quiescent for about half an hour, when it began to move rapidly, shooting out rays as it approached the zenith, forming a pale but imperfect corona with its culminating point in Cassiopeia, This is the first occasion of such activity at such an early hour. It was of short duration, however, and was succeeded by the usual diffused light or luminous haze occasionally interspersed by bands and patches of deeper light. Several bands developed about 1 a. m. of the 24th, and afterwards became numerous, forming generally low down in the NE, and moving slowly toward the zenith, where they generally became broader and more diffused, sometimes dividing into two or more. The brightness seldom exceeded 2, but the haziness of the sky dimmed it to a great extent. At 7 a. m. all that remained was a rather bright light low down in the SW. behind the clouds, with patches of luminous haze in various parts of the sky. Although the phenomenon at this time showed no appearance of intense activity, yet the magnets were greatly disturbed. The horizontal force was greatly increased, as was also the vertical, while the needle of the declinometer was deflected first to the W. and then to the E., the former deflection taking the magnet out of the field of the telescope. Very little brilliancy was exhibited until about 1 p. m., when there was quite a burst of light and intensity. Rays, bands, convoluted curtains, and flashes of quivering light appeared over the greater part of the sky. Numerous rays shot up from all sides toward the zenith, but no proper corona was formed. Magnetic disturbance lasted all through the display. which finally disappeared about 2.15 p. m.

December 24 and 25, 1881, 9 p. m. to 10 a. m.—Patches of light low down in the NE., which broadened out into luminous haze, that extended slowly upward toward the zenith, shooting up occasional rays, which about 1 a. m. developed into a faint arch near the zenith. Other arches increasing in brightness succeeded this in quick succession until about 3 a. m., when the light was spread all over the sky, sometimes as curtains and bands and broken segments of arches, sometimes as large floculent masses looking like cumulous clouds illuminated by transmitted light. There were periods of quiescence alternating with brief displays of activity. No colors, however, were observed beyond the usual white and yellow, but these at times were very intense, reaching the maximum of brightness. After lasting for about an hour the display gradually subsided, and until 7 a. m. only occasional patches and bands appeared irregularly in various parts of the sky, but being mostly brightest in the W. From 7 to 8 a. m. the brilliance rapidly increased. Curtains,

arch, quiet t rose very of the 22d er it passed eter part of o time, and le at 1 p. m. in the NE. c. a. m., 23d. After this it eeded faint to particuoint almost e, the total

XE., which shooting up her arches e light was ches, sometited light, s, however, e, reaching brided, and of the sky, Curtains,

broken arches in every variety of convolution spread extensively over the sky, being propagated from the E. toward the W., and being brightest in the S. and W. Declination and vertical force increased and the horizontal intensity decreased. Ended at 10 a. m.

December 26, 1881, 1 a. m. to 10 a. m.—Very pale and irregular in shape and position. Seldom a complete arch appeared, and when it did its outlines were mostly very undefined and its continuance very brief. The sky was very hazy, so that it was only near the zenith that the phenomenon could be observed. At 9 a. m. a narrow but bright arch formed in the NE. and rose rapidly toward the zenith. As it rose it displayed a peculiar intermittent kind of activity, especially when it reached the zenith. Pulsations of intense vibratory motion passed along it from NW. to SE. in direction of its length at short intervals, each succeeded by brief intervals of quicseence. Once it reached the zenith it began to fade, or, rather, its outlines became indistinct, and it slowly passed down to the southward, when it changed into the usual luminous haze. The magnets at this time showed great increase in vertical force and decrease in horizontal intensity. Previously, at 6 a. m., they showed another period of disturbance, although scarcely any aurora was visible. There was at no time a brilliant display, but during most of the time the magnets were as much disturbed as during the most brilliant ones.

December 26 and 27, 1881, 11 p. m to 7 a. m.—A faint arch running from N. to E. very low down appeared behind the haze, and afterwards traces of light and portions of bands were observed in various parts of the sky near the zenith, until about 7 a. m. the 27th. The night was however so cloudy and hazy, that its characteristics could not well be observed.

December 27 and 28, 1881, 11 p. m. to 1 p. m.—A faint diffused arch appeared low down in the NE., which remained with but very little change for several hours. This aurora lasted with several periods of intermission until 1 p. m. of the 28th, but there was no brilliant display of either light or color. Occasional arches and parts of arches formed in various parts of the sky, but they were always pale and of brief duration. The only noticeable peculiarity of this aurora was the extent and brightness of the luminous haze. It covered most of the sky, and at times assumed a peculiar stratified appearance, like numerous polar bands very close together. Sometimes it broke up into patches of deeper density, and sometimes was so diffused as to almost disappear. At 5 a. m. the magnets were considerably disturbed, the unifilar being strongly deflected to the east.

December 29, 1881, 4 a. m. to 2 p. m.—First appeared as narrow bands running from the SE, towards the zenith, which soon rose and spread over the sky assuming the usual hazy and diffused character. Bands, rays, and partly formed arches appeared from time to time, but presented no marked features worthy of notice. There was no apparent internal motion and no variety of color. At 8 a. m. it was at its brightest, and coverent the greatest extent of the sky, but did not reach a brightness exceeding 2. The magnets were however a good deal disturbed, the vertical force and castern declination increased and horizontal intensity decreased. These conditions continued with but slight change until 10 a. m., after which the magnetic disturbance decreased, and the auroral light faded away, but did not entirely disappear. Traces of it were visible until about 2 p. m.

December 30, 1881, 1 a. m. to 1 a. m.—Traces of aurora seen through haze at 1 a. m., but it was too cloudy to observe either its beginning or ending.

January 1, 1882, 7 a. m. to 7 a. m.—Traces of aurora bands seen through the clouds at 7 a. m. Beginning or ending not observed, owing to cloudiness of weather.

January 2, 1882, 4.15 a. m to 10.30 a. m.—Narrow arch running from W. to SE. low down toward the southern horizon. Very little motion, and brightness about 2. It rose very slowly toward zenith where it became broken up, and assumed the diffused character. After this it maintained a fluctuating existence until 10 a m. At 8 a. m. a few rather bright streamers appeared in the N., and extended themselves across the sky toward the SE. but soon faded away. Magnets were slightly disturbed.

January 3, 1882, 7 a. m. to 9 a. m.—A few patches appeared at intervals between 7 a. m. and 9 a. m. None of them were bright; all were irregular in shape and seemed to start from no point in particular but apparently seemed suddenly to burst out of the sky and after flickering for a short time, disappeared. Magnets were slightly disturbed.

H. Ex. 11---47

January 4, 1882, 2 a. m. to 9 a. m.—Faint arch low down in the NE., searcely distinguishable from a long band of cirrus cloud which after languishing for a short time disappeared and did not reappear until 7 a. m., when a few fugitive bands appeared in the NE. which soon developed into a well marked curtain (brightness 3). There was but little vibratory motion and not much change in color. Declinometer needle deflected slightly to the E. and vertical intensity increased, accordance and occasional patch or ray, lasting generally only a few minutes.

9. I disappeared at 9 a. m.

Fanuary 5, 1882, 1 a. m. to 8.30 a. m.—Occasional rays, curtains and patches of light from 1 i. m. to 7 a. m., none very bright and all of brief duration. There was very little apparent metrop. The various curtains and patches did not usually have a regular forward motion in any direction. They appeared to burst out of the sky, fluctuate for a few minutes, and then disappear. At 7 a. m., however, an irregular curtained arch appeared ascending from Taurus to Boöfes with its center slightly N. of zenith—It exhibited momentary bursts of vibratory motion and was brighter at 1 southeastern en 1. Its brightness was about 2. The magnets were greatly disturbed, the horizontal force decreased, the vertical intensity greatly increased, and the declination to E. also increased ended about 8.30 a. m.

January 5 and 6, 1882, 11 p. m. to 3.30 p. m.—Appeared as a narrow pale arch running from Y to SE., with its center in Gemini. It lasted only a short time, and exhibited no apparent metrod. It reappeared at rather lengthened intervals, mostly low down in the N. and NE., and never very

bright or high, and was last observed at 3,30 p. m.

January 6 and 7, 1882, 11 p. m. to 7.30 p. m.—Luminous haze all round the horizon, with a d. 1 circle of about 5.1 width, corresponding to the well-known dark segment below it. From this harmonic rays, so faint and ethereal as to be almost imperceptible, shot up towards the zenith. In fact, it appeared as if a series of pulsations or ethereal quiverings, which almost cluded the group of vision, passed over the sky in a kind of rythmic unison; the converging point of motion of the zenith. This phenomenon continued until the light of the moon, which soon rose, rendered invisible. Occasional cartains and arches, mostly pale and irregular in shape, followed. At 7 p. m. a very pale arch ran from NW, to SE, through Taurus and Boötes, and after remaining a short time it slowly faded away.

dawn my 8, 1882, 1 a. m. to 10.40 a. m.—Appeared first in the usual form of a faint still of his extending from N. to SE., and possessing a slow upward motion. At 2 a.m. it had risen to the zenith, when it divided into six or seven narrow bands, brightness about 2, with consider 40% vibratory motion, but no streamers. After passing the zenith it became diffused and soon disc pearen. Bands and curtains, patches of light, and detached rays succeeded in quick succession. appearing in various parts of the sky, but none were very brilliant or of long duration. The cowere intervals of quiescence when scarcely any light, other than the usual luminous haze, was vi ible, and this was generally by an interval of display more or less brilliant until about 10 ... . .. when there was quite a brilliant one. Several rays appeared in the NW, and the SE,, which proagated the vely's toward the zenith where they met, forming an irregular but brilliant was eshiofier, an extremely rapid motion. Numerous short rays shot up and whirled to and sof park, yellow, and green flashed out, convoluted curtains appeared and rolled and Lengthali or error, exacting to and tro, at if hung out by invisible hands, but all changing was very hard to point their place. The brightness at this time was fully to rap. av v be each to fade; in about twenty crimites all had disappeared.

the declination was irregular, being sometimes easterly and sometimes westerly. After this display was over the light greatly faded and finally disappeared about 10 a. m.

January 9 and 10, 1882, 10 p. m. to 1.50 a. m.—Appeared as a quite still arch, low down in the NE., with the dark segment distinctly visible below it.—About 12 m. it had risen almost to zenith and grown considerably brighter, but at no time did the brightness exceed 2. There was some slight vibratory motion, but it soon began to fade, and after nearly disappearing brightened up and formed a broad irregular arch, running from the NW. through Cygnus, through the zenith and down through Canis Minor, displaying considerable vibratory motion; this was at 1 a. m. of the 10th.—At 2 a. m. all had disappeared. Magnets very little disturbed.

January 10 and 11, 1882, 11 p. m. to 8 a. m.—Traces of hazy light appeared low down in the E.; afterwards succeeded by several faint arches, which rose slowly and generally faded or became very diffused as they approached the zenith. At 3 a. m., 11th, a bright broad arch ran from NW. to SE, through Cygnus, Ursa Major, and Leo. Several whorls and patches succeeded until about 8 a. m., when all had disappeared.

January 13, 1882, 11 p. m. to 12 m.—Auroral arches observed through the clouds and drifting snow near the zenith between 11 p. m. and 12 m.

January 14 and 15, 1882, 10 p. m. to 12 midnight.—Pale narrow arch appeared low down in the NE, which rose slowly and as it approached the zenith was succeeded by others below, flocculent patches and much diffused light at the same time in various parts of the sky. This condition of arches, patches, and bands and diffused light constantly changing, but the general features remaining the same, continued till 10 a.m., after which they became paler and entirely disappered at 12 m.

January 15, 1882, 10 p. m. to 6.30 a. m.—The usual low arch appeared in the NE, with the dark segment for a time clearly visible, but as the arch arose the segment disappeared. This arch rose very slowly, but presented an appearance of an extremely rapid internal quivering while numerous short rays fringed its upper side which swayed and flickered like the flame of burning alcohol. A succession of similar arches followed until 5 a. m. They were all pale, and after the latter hour only a few patches were visible, and all had disappeared at 6.30 a. m.

January 17, 1882, 1 a. m. to 7 a. m.—Faint lov arch in NE, remained stationary for a time and then rose slowly and became broken up and diffused; sometimes it entirely disappeared for a time, reappeared as occasional patches and curtains which maintained a fluctuating existence until 7 a. m. when it had disappeared.

January 17 and 18, 1682, 10 p. m. to 8 a. m.—Quiet arch low in NE. It rose very slowly, and about 2 a. m. 18th, had reached the zenith where it had broken up into sundry bands and patches which seon faded away into an extensive luminous haze which continued until about 8 a. m.

January 19, 1882, 1 a. m. to 4 a. m.—Traces verble through rents in the clouds near zenith at 1 a. m. and 4 a. m.

January 20, 1882, 4 a.m.—Several bands is—e zenith visible through rents in the clouds at 4 a.m.

January 21, 1882, 4 a. m. to 4.30 a. m.—At 4 c. in, the sky which had been previously cloudy suddenly cleared up and a pale arch appeared excluding from NW, to south and elevated about 26° above the SW, horizon. After rising slowly a few minutes it suddenly burst into a state of intense activity, and at the same time move? A silly toward the zenith, the distance between the head of Orion and the zenith being passe and in about five minutes. Numerous swirling thys tandout shooting upwards and apparent acconverging toward Capella. A kind of compressed or foreshortened corona was formed, and from the hapidly changing swirls and convolution, various brilliant colors flashed out, green, pink, rose and yellow being the prevailing times. The head of a transmits were strongly deflected. The head will be reased and the easterly declination increased. The sky became clouded at 4.20. No more was all served.

January 23, 1882, 12 a. m. to 40 a. m.—A patch of flocculent light appeared near the Lee of a in the NE. Others soon after appeared and so year times approached the arch form until the matter that time there was a period of cessation until 4 a. m., when a faint of heavy and to the flowing and more observed the enith, where it divided into a broad so he of the latter of flow N, to the Art is a time the dimes of condition have of the discount of the condition.

January 23 and 24, 1882, 10.30 p. m. to 8 a. m.—A few patches low down in the NE. soon roso and formed a pale broad arch with its center touching Ursa Major, which soon faded away and did not appear until about 4 a. m. of the 24th, when a low pale arch appeared to the southward with its center in Orion. This slowly rose until it approached the zenith, when it became stationary and remained in an irregular hazy condition until about 8 a. m.

January 25, 1882, 2 a. m. to ——.—Patches of light appeared low down in the E., which slowly gave place to a series of faint irregular arches running from the N. to NE., which mostly faded away as they approached the zenith into a faintly luminous baze. Several bright whorls appeared in the E. at various times, but did not extend higher than 30° from the horizon. Time of ending not reported.

January 27, 1882, 4 a. m. to ——. —A very pale band running from NW. to SE., and rising very slowly, reached the zenith, where it divided into pale, very broad, and ill-defined arches, and at 6 a. m. nothing was visible except a few patches of floculent and a great deal of diffused light. Termination not reported.

January 28, 2 a, m, to 2.30 a, m,—A few faint rays appeared low in the N, from 2 a, m, to 2.30 a, m,

January 29, 1882, 4 a. m. to 7 a. m.—A faint ray rose from the N., and after reaching the zenith curved to the eastward, forming a broad irregular arch. At 5 a. m. the N. end had faded away, or rather seemed to be drawn up towards the zenith, when it became twisted into a series of whorls and convolutions; the other end at the same time extended in irregular curves to the SE.—There was a slow motion to the northward, the light at the same time fading away. At 6 a. m. there was a repetition of the phenomenon, but at this time the convolutions and whorls extended from the remith down towards the N. horizon.—Last reported at 7 a. m.

January 29 and 30, 1882, 10 p. m. to 8 a. m.—Faint arch from N. to E., with altitude of about 16, a few streamers at its N. end. It rose slowly in the usual manner until it reached the zenith, when it slowly faded away. Others of a similar character followed at intervals, accompanied by flocculent whorls and much diffused light. Occasionally several bands passed through the zenith at the same time, always from the NW. to SE., but none of them were brilliant. Last observed at 8 a. m.

January 31, 1882, 3 a. m. to 6 a. m.—Faint patches of light appeared low in the NE., which scon arranged themselves into the usual form of a faint broad arch, which rose slowly, and had reached the zenith at 4 a. m., when it looked exactly like an immense tail of a comet, curving from the NW. to the SE. horizon.—It soon afterwards faded, and was succeeded by faint nebulous light in various parts of the sky, chiefly in the NE.—Last reported at 6 a. m.

February 1, 1882, 6 a. m. to 9 a. m.—A few very faint arches were formed, differing from the usual character in the circumstance that their general direction was from N. to S.

Pebruary 2, 1882, 1 a. m. to 7.30 a. m.—First observed as a narrow wavy band, running from N.W. to S., with an altitude of about 50°. At 2 a. m. it had become lower and more sinuous and exhibited a rapid vibratory motion, its lower edge being slightly tinged with pink. It soon afterwards faded away, and was succeeded by occasional patches and whorls until 7.30 a. m., when it entirely disappeared. For the last few days the light of the aurora has been much dimmed by the brilliance of the moon.

February 2, 1882, 11 p. m. to ——.—At this hour a few streaks and patches were observed in the E., but the haziness and cloudiness prevented further observation.

February 4, 1882, 11 p. m. to 9 a. m. February 5.—Low arch in the NE., indefinite outlines, and rising very slowly. At 12 m. a few streamers appeared at its N. end, but did not continue long. Several similar urregular arches appeared up to 3 a. m. Streaks, patches, and bands appeared also at intervals during the same time, but afterwards it was too cloudy, and nothing more was observed until 9 a. m., when a few streaks were seen through breaks in the clouds in the zenith-

Fibruary 5, 1882, 11 p. m. to ——————At this time traces of auroral light were visible low in the NE., but the weather being cloudy nothing was had but an occasional glimpse through breaks in the clouds, so it was impossible to give a description. Magnets read very irregularly.

innes, and inue long, appeared more was zenith, ow in the breaks in February 6, 1882, 10.30 p. m. to 9 a. m. February 7.—An irregular but rather bright arch appeared low in NE., with faint rays occasionally shooting from its N. end. Occasional arches followed, but they could not well be observed, owing to cloudiness. Last observed at 9 a. m. of the 7th. Magnetic needles very irregular.

February 7 and 8, 1882, 11 p. m. to 7 a. m.—Faint arch low in NE., rising slowly. The cloudiness of the sky prevented observation, but occasional glimpses were had of arches near the zenith up to 7 a. m. of the 8th.

February 8 and 9, 1882, 10.30 p. m. to 11 a. m.—Beginning of display could not well be observed in consequence of haziness of the sky, but occasional glimpses were had until 3 a. m. of the 9th, when there was quite a brilliant interval. Several bands passed through the zenith and on each side of it, running from N. to SE. The haziness was such, however, that it was only near the enth that a distinct view could be had. It was still visible from time to time until about 11 a. m.

Tebruary 9 and 10, 1882, 10:30 p. m. to 10 a. m.—Commenced low down in the N. and extended as low arches towards the SE, and SW., and afterwards rose to the zenith, but the haziness of the sky still obstructed observation. Last seen at 10 a. m.

February 10 and 11, 1882, 11 p. m. to 10 a. m.—This was the most brilliant display that has been observed for some time past. It commenced the usual way, as an irregular arch low in NE., anch rose slowly, and became brighter as it rose towards the zenith, but after reaching that point it immediately faded away. This was followed, in rapid succession, by other arches, brighter and broader, which mostly faded away on reaching the zenith, or broke up into numerous fleecy masses of light, which often spread over the greater part of the sky, and which, though individually not of great brightness in the aggregate, yielded an amount of light approaching that of a full moon. It differed, however, from moonlight in its more diffused character, but still large objects, over a ande distant, were clearly visible. Several times during the night arches were formed, which deserved the name much better then apporal arches usually do. Instead of being large and concentric or parallel, as is usually the case, they were end to end, small, and resting on long straight columns, running down to the horizon, as many as five appearing at one time. One in SE., one in the E., one in the NE., one in the N., and one in the NW. In most cases two arches sprang from one column and went in opposite directions. None of the arches were, of course, exactly symmetrical, but sometimes they approached it closely. Faint tints of pink and green were occasionally visible, but the prevailing color was yellowish white. The magnets displayed much irregularity.

February 12, 1882, 12 a. m. to 11.30 a. m.—Began very faint and went through the same succession of changes, but with much less brilliancy than last night. After 9 a. m. it was very irregular and mostly faint, and finally disappeared at about 11.30 a. m.—The needles, as usual, disturbed and irregular.

February 12 and 13, 1882, 11.30 p. m. to noon.—Began as usual faint and low in the NE., but did not increase much in brightness or become very extensive until after 3 a. m. of the 13th. After that hour arches, bands, and fleecy masses of light, very extensively distributed, succeeded each other quite rapidly. There was very little appearance of the parallelism usually observed, and seldom more than one band or arch appeared at the same time, but as each arch which retained its shape approached the zenith it generally became very broad and hung overhead like a great clonicated canopy, and again it stretched across the sky in graceful convolutions like an immense scroll, but the commonest form was that of irregular detached masses which spread over the greater part of the sky and faded into a sort of nebulous haze. The general motion was from N. to S. and tather slow. The magnets read irregularly, but there was not very much disturbance even when the whole sky was nearly covered with light. Ended about 12 noon.

Fibruary 14, 1882, 12.30 a. m. to 10 a. m.—Began as faint irregular patches low in NE., aftermids succeeded by the usual series of irregular arches, bands, and patches, but at no time was the 1 pby very brilliant; less so than on the two last preceding evenings. Last observed at 10 a. m.

Leberary 14 and 15, 1882, 11.45 p. a. to, 10 a. m.—Began as a faint light low down on the N. and NYE, horizon, appearing like twilight behind the haze and light clouds. Several arches afterwards appeared in the zenith through the clouds, extending in the usual direction from NW, to SE,, but the presented no marked feature other than the slowness of their movement. This slowness of motion seems to be increasing as the brilliance of the display decreases. Maintained a fluctuating

existence until 10 a.m. of the 15th, after which it was no more seen. Needles, as usual, reading

February 15 and 16, 1882, 11.30 p. m. to 7 a. m.—Began as faint light behind the clouds on large NW. horizon, and afterwards an occasional band or arch was dimly visible in the zenith through the clouds and were apparently for the most part stationary, and the last time they were visible was 7 a. m. of the 16th.

February 17, 1882, — to 10 a.m.—Time of beginning could not be ascertained, owing acceptable cloudiness, nor could the extent be observed from the same cause. Was last seen at 10 a.m.

February 18, 1882, 1 a. m. to ——.—First observed at 1 a. m., but owing to the increasing cloud incs no proper observation of its extent or brilliance could be had. Bands and whorls were some times visible in and near the zenith, where they seemed in or very near to the haze or thin 1 1. To the eye they seemed below it, but this could not be really the fact or more of their length at 1 have been visible than what appeared in the zenith. After 5 a. m. the clouds were too the form any light to get through.

Fibruary 19, 1882, — to ———Beginning or ending could not be observed, owing to be cloudiness. The display seemed to be quite brilliant, however, at times as its light could be through the clouds, although no stars could be seen at the time. The magnets were, as used by the clouds of the clouds of the clouds of the clouds.

nider this disturbed.

is a congress, to the constant of heginning not observed, owing to the clonests and only occasional glimps, s of it were had during the night, when in the zenith. Never the state of the constant of the cons

Peteracy 10 and 21, 4882, 11.30 ρ. m. to 10.30 a. m.—This was a rather beilliant display accidinated an e-what more motion than has been usual for some time. It commenced as pale not loss patches, sometimes in the NE., in N., and NW., but always rose rapidly and culminated in the zero, in after reaching which it remained stationary for a time, sometimes flashing and gyrand, and then gradually fading into a luminous haze to the southward. At 5 a. m. of the 21st, the whole sky for about 60°, on each side of the zenith, was filled with light which looked like a harmous cloud. There were periods of activity lasting about half an hour, with similar intervals of quiescence, which constituted a succession of waves which culminated in or near the zenith. Continued until obliterated by daylight, about 10.30 a. m.

soon are and formed a narrow, faintly luminous arch and rose slowly to the zenith, where it broke up into numerous patches which, after a time, faded away in a kind of luminous haze to the senting ward. Faint arches and patches thus succeeded each other at short intervals until a little become

the dawn, when they entirely faded away.

February 23, 1882, 2 a. m. to 10.20 a. m.—Begun as usual, very faint in the NE., and the usual succession of phenomena occurred. Narrow arches were found to be succeeded by whorls, patelo and nebulous haze, but on the whole there was more activity than has been displayed for successional rays appeared and several imperfect coronas were formed. At 5.15 a. m. of sections was quite brilliant. Numerous faint rays appeared converging in Ursa Major, then S. c. zenith. The motion was very rapid and some flashes of color appeared—green, yellow, and test zenith arches generally appearing as patches in the S. or SE, and were propagated to the northward. The display lasted, with periods of intermission, till daylight. The magnets were considerable dispatched.

February 23, 1882, 11.30 p. m. to ——.—Began in the usual manner in the NE., but althor, see etc. taint corona were formed they were not so brilliant as on the previous evening and evens was besides considerably more diffused light and luminous haze.

February 21, 1882, 12:30 a. m. to 10 a. m.—Appeared first as faint patches, which developed and faint, narrow bands and irregular arches, and faded away into the usual luminous haze. At the time was this display very brilliant, nor did it apparently pass through any of the active stands. The bands often broke into detatched masses which were scattered irregularly over the sky. Despected before the advance of the dawn at 10 a. m. The needles were disturbed.

assumed the arched form so common on other nights. Irregular-shaped masses of hazy light appeared in various parts of the sky, principally in the N. and SE., which extended imperceptible upwards until they formed broad cloud-shaped masses in or near the zenith, and then after a time faded away into the usual luminous haze. Needles disturbed. Disappeared before daylight; who if to a. m.

Proceedings 26, 1882, 6 a.m. to 7.30 a.m.—A faint patch appeared in the SE, and one in the N value a soon extended towards each other and formed a faint arch, which rose slowly until it reached the zenith, when it broke up into irregular-shaped masses, which arranged themselves round the zenith. In form almost circular. A period of activity then cusued, and numerous short rays shot of red and converged directly overhead. While in this condition it was simply a corona with the sening. A few tints of green, rose, and yellow were observed during this active period, but they were of very brief duration. The display lasted about fifteen minutes, and then sendually faded, and was no more visible after 7.30 a.m.

If we y 27, 1882, 3 a. m. to 7 a. m.—Impossible to determine the beginning or end of this was a strong to the cloudiness of the sky. It was occasionally seen until 7 a. m. The magnets are the tyled disturbed.

the erg 28, 1882, — to — ... —Too cloudy to permit observation. Auroral light was only some erge, near the zenith to the NE. Needles somewhat disturbed.

7. 4. 4. 1882, 7 a.m.—Seen through the clouds in the SE, at 7 a.m., but the rest of the night the acceptance of the second of

2, 1882, 9.15 a. m. to ——.—At 9.15 a. m. the clouds rolled off for a few minutes and left and the bright auroral band visible, passing through the zenith in a NW, and SE, direction.

3, 4882, 3 a. m. to ———Commenced faint and irregular, and at 4 a. m. there were two arches at right-angles to each other, the brightest running from X. to SE. Soon afterwards they became broken up into segments, and soon faded into the usual luminous haze, and as the sky conditional and obscured by clouds the termination of the display could not be ascertained. The many is, as usual, were agitated.

... vl. 4 and 5, 1882, —— to ——.—On the 4th and 5th, especially the former, there was magneticilistic bance at times, but being cloudy no aurora could be seen.

Take 6, 1882, 2 a. m. to 8 a. m.—First observed about 2 a. m., when three somewhat sinuous rays or bands extended from N. to 8E, about 10° west of zenith. Between 2 and 3 a. m. there was gate a brilliant interval when the sky in and near the zenith was covered with fleecy cloud-shaped aurora. There was very little apparent motion, and after 3 a. m. there was a constant electronse in brilliance, and after 4 a. m. but little light was seen. The last was seen at 8 a. m., when a faint ray was visible in the W.—The increasing cloudiness, however, prevented its termination from being observed.

Which 7, 1882, 1 a. m. to 9 a. m.—Commenced as faint rays in the N. and SE., which soon formed a narrow arch with a few streamers at its northern end. Occasional arches and scattered streamers followed at intervals, but none were very brilliant and there was much less of the luminous haze which has been so common during last month. After 4 a. m. only an occasional ray appeared until 6 a. m., after which no more were visible until just as the dawn began to appear at 9 a. m. at 15 a. m. local time), when a few rays appeared for a few moments just above the line of light in the E. and parallel to the rays of light coming from below the horizon.

Fixeh 8, 1882, 5.15 a, m.—The night was cloudy and only one glimpse of auroral light was had at 5.15 a, m.—The magnets were considerably agitated.

Merch 9, 1882, 3 a, m, to 8 a, m.—Commenced about 3 a, m, while the sky was partly covered by clouds. There were occasional displays of streamers, irregular curtains, and arches, accompanied by considerable motion. The streamers were long, pale and slender, and sometimes approached the coronal form converging towards the zenith. The prevailing character, however, was the diffused form distributed in patches all over the sky; the light threw the intervening chard-anto-strong relief and seemed on many occasions similar to the diffused brightness of the dawn. The general motion was from N, to S,, but it was mostly very difficult to determine its direction owing to the cloudness and the extensive distribution of the light. The sky became entacky cloudy after z a, m, and no more of the display was observed. The magnetic water cay

much disturbed and the perturbations were more than usually intense after sunrise and continued up to noon, local time.

March 10, 1882, 3 a.m.—Commenced about 3 a.m., but very little of it was seen owing to the cloudiness. There was considerable magnetic disturbance.

March 12, 1882, 3 a, m, to 5 c, m,—The usual time of commencement for some time back has been about 3 a, m, (10 p, m, local time). This was quite a brilliant display while it remained visible. At 4 a, m, there was a very broad irregularly convoluted arch through the zenith from NW, to SE, with a number of scattered whorls. There was little apparent motion, but still constant change; a little before 5 a, m, the clouds came suddenly up and obscured the sky, but the thinner portions were rendered quite luminous by the light behind them at 5 a, m,, but it was not visible afterward. The magnets were disturbed.

March 13, 1882, 1 a, m, to 9 a, m,—Appeared as soon as the twilight had faded sufficiently to permit it to be visible as a broken and sinuous arch from N, to 8E, with an elevation of about 45, which soon afterwards reached the zenith where it remained stationary for a short time, and then passed to the southward. Other arches followed, mostly broken and bright in places, with occasional rays shooting toward the zenith. The general motion was, as usual, from N, to S,, but most of the arches that appeared to swing round on their northern end as a pivot until they reached position running from N, to SW,, and an elevation of about 35° or 40°, when they became stationary. After 6 a, m, they became paler, but did not wholly disappear until the twilight rendered them invisible about 9 a, m, (4 a, m, local time); but slight magnetic disturbance.

March 14, 1882, 6 a. m. to 9 a. m.—Probably extensive, but the clouds were very dense and mobservation could be had. At 6 a. m. and 9 a. m. light shone through near the zenith. The needles were slightly disturbed.

Now h 15, 1882, 1 a. m. to 10 a. m.—Began probably during daylight, for it appeared as a narrow arch high up even before twilight had faded. After this, arch succeeded arch until the approach ing daylight rendered them invisible. The movement of the arches was in general from N, to S. Sometimes, however, after passing the zenith some of them seemed to pause and retrogade toward the  $N_n$  at the same time casting out numerous short rays from their upper side and exhibiting a good deal of motion. Sometimes tints of green and rose were visible, but they were faint and tranient. Several of the arches on reaching the zenith expanded into bread, irregular canopies which extended down on all sides as much as 25°. Sometimes several arches and irregular shaped curtains appeared at the same time, and faint, almost invisible, rays shot up to the zenith. At times the arches became broken up into numerous broken rays scattered over the sky, but close enough to gether and with enough parallelism to give them a very peculiar appearance, like patches of luminous send swept along by the wind; in fact a kind of luminous or auroral drift. Another peculiarity of those arches was that they did not rise from a low point near the horizon, as was usually the case earlier in the winter, but first appeared as faint rays in various parts of the sky, mostly in the N, and SE,, and then rapidly developed into arches mostly rather brilliant but mostly very narrow. There was besides a good deal of the usual haziness, especially towards the south ward after the arches had passed the zenith. The magnets were somewhat disturbed, but not remarkably so.

March 16, 1882, 3 a. m. to daylight.—This was a much more brilliant display than has occurred for some time; the degree of brightness was higher, there was more activity, and the variety of feature was greater. For some weeks back the successive phases of the phenomenon followed each other rather slowly, and even the culminations were not characterized by much intensity of brilliance, but on this occasion it was different; there was rapidity of motion both collective and vibratory, and brilliant culminations. The arches, bands, and whorls were very numerous and very irregular both in position and shape, the perfectly arched form being seldom reached until the light masses had passed the zenith and become pale to the southward. Sometimes the whole sky overhead was covered with a great field of fleecy light, which after passing through a variety of changes mostly seemed to fade away from the center, while the surrounding margin seemed to sink down towards the horizon like a great ring, which, as it slowly faded, gave birth somewhere in its northern or southeastern quarter to rays or wherls which soon developed into new arches or bands and new phases of the phenomenon. There were numerous rays, fringes, and curtains,

it not re-

occurred caracty of followed ensity or etive and rons and ied until he whole a variety cenaed to mowhere arches or currains, and often small canopies or imperfect corone were formed in the zenith. The culminating point was at 6 a. m., when a brilliant canopy of dancing rays, circling whorls, and waving banners covered the sky overhead and extended down on all sides 30 or 40 degrees. The culminating point was in Ursa Major, and the whirling, gyratory motion was not in the plane of an arch, but in that of a circle having its center almost in the zenith. There was but little variety of color—pink, rose, and green appearing occasionally at the base of the rays and columns. The brightness was at the maximum, the ice surface along the horizon out to sea being pretty clearly visible. The magnets were greatly disturbed.

March 17, 1882, 4 a. m. to 7 a. m.—This was not an extensive display, nor was it of long duration. The arches were not numerous nor very bright, and were very irregular in shape, more like great whorks or scrolls than arches. The only noticeable feature about them was that they never passed the zenith to the southward, but generally faded on reaching it. They commenced probably in the north and extended towards the SE., but displayed little motion and but few rays appeared. After 7 a. m., or 2 a. m., local time, it was no more visible. The magnets were very slightly disturbed.

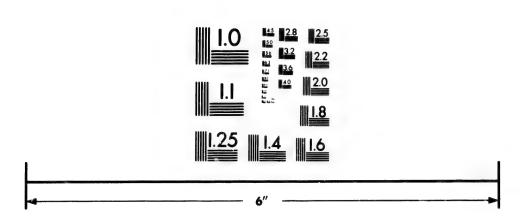

darch 20, 1882, 3 a. m. to 8 a. m.—Began probably some time earlier than 3 a. m., as imme-Eately on the clouds rolling off, a bright sinuous but broken arch was visible extending from NNW, to SE., and passing close to the zenith. After this for three hours there was quite a rapid since sion of bands, arches, and whorls, accompanied by much internal or vibratory motion. The ereal motion of the arches was from N. to S., but on several occasions they seemed to part in the middle when near the zenith, and the broken ends became folded up like a rope that had then at a high tension; generally, however, on reaching the zenith the arch broadened or divided up into several, or spread out into an immense field or canopy, dim at first in the center, and brighter round the margin. When this form was reached, numerous rays shot up from this bright margin towards the zenith, where a more or less bright but irregular shaped corona was formed which swirled and swayed and assumed a great variety of form, but was always of brief duration. At 4 a. m. (11 p. m. local time), the display had reached its maximum, where there was an immense canopy covering a great part of the sky, numerous streamers, several imperfect corone, and great vibratory activity. There were numerous flashes of color at the base of the streamers; ted and yellow were the predominant colors. This period did not last more than fifteen minutes, and was succeeded by the usual hazy condition of the sky, with a whorl and patch here and there. At 6 a. m. there was another period of activity, similar to the above, but on a smaller The activity was probably equal, but the brilliance and extent of their display was much There was one bright arch extending from about N. to SE., through the zenith with much point light on each side of it. Its center when overhead broadened, and being like a curtain waying to and fro, and looked remarkably near. After slightly passing the zenith it remained tationary for some minutes, and its upper side became very jagged or serrated, and seemed as if a trong wind were blowing against it, while projecting points protected it in front. This condition remained nearly ten minutes, and was indeed very peculiar. The jagged appearance was too irregular and too persistent to be caused by a series of rapid undulations, and conveyed very strongly the idea that a strong wind was blowing across the arch. After this there was very little activity and but few arches, and all faded at the approach of the dawn. The magnetic disturbance was very great, especially during the appearance of greatest activity. There was great decrease in horizontal force and increase in vertical intensity, and a large increase in declination to the eastward.

March 21, 1882, 2 a. m. to daylight.—Not a brilliant display, but there was great rapidity of change and motion. There were very few perfect arches, the general form being that of whorls and patches, which were scattered nearly all over the sky. It was last visible at 9 a. m. (4 a. m. local time), when there was a period of great activity, the flashing of the light being faintly visible overhead, notwithstanding the brightness of the twilight. There was very great magnetic distribute, the greatest we have had since this year commenced. The needles were very much agitated, but at 9 a. m. the agitation became extreme; the bifflar needle went far out of the field and remained for two hours out, the force greatly decreased. The unifilar was deflected 25 30°

STATE OF THE PARTY

from the meridian towards the E, and the dip increased about 2° above its average amount,  $|\psi_0|$  needles did not get back to their normal condition until about 4 p. m.

March 22, 1882, 3 a, m. to 7 a, m.—A faint and irregular display, with very little motion few faint arches developed in the NE, and rose slowly to the zenith, but as clouds lay along to the southward the light soon became lost behind them. At 7 a, m. the sky was completely overcome which rendered it impossible to determine whether the display continued till daylight or not. The needles were but slightly disturbed.

March 24, 1882, 4 a. m. to ————————Very irregular and not brilliant, but as the sky was medical cloudy until the coming of daylight it could not be well observed. The needles were only slightly, distarbed.

March 25, 1882, 3 a. m. to 8 a. m.—Faint and very irregular, but could not well be observed, owing to the cloudiness; was last seen at 8 a. m.; needles reading irregularly, but not much at tated.

March 27, 1882, 2 a. m. to daylight.—Rather more brilliant than the preceding one. The abelia were much more numerous and bright, but the brightness of the moon dimmed them conside a 7. The arches mostly formed in the NE., but seldom rose higher than the zenith until about 7 a m. when they began to pass to the S. At 8 a. m. (2.43 a. m. local), there was a bright convolute a curtain in the NE., just outside of the boundary line of the advancing twilight, which exhibited much lateral and vibratory motion and the needles were considerably agitated.

March 28, 1882, 3 a. m. to 6.15 a. m.—The beginning of auroras cannot now be determined with much correctnes; owing to long continuance of daylight. They are generally firs; some about two hours after sunset and generally high up near the zenith and at present the brightness. of the moon dims their brightness considerably. This display was first observed as a pale street rising vertically from SSE,, and occasional pale arches followed without exhibiting much brillians. and mostly faded out in the zenith. At 6 a. m. (12.43 a. m. local), a convoluted arch appeared to the southward at an elevation of about 50° where it hung for a short time and passed through a var. of changes until about 6.15 a.m., when it suddenly moved upwards to the zenith where it follows: a very brilliant corona and exhibited the most intense activity, swirling and gyrating with great rapidity. The principal motion was not that of detached vibrating rays but that of a kind of a tertwined curtain or fringe which was bent back and folded on itself into a kind of true lover. knot, which seemed to hang out of the sky. The vibrations followed each other from right to left in direction of length of the figure, passing round every turn and convolution and coming back to their starting point with too great a rapidity for the eye to follow. There was great variety of color from the intensest red, yellow and green through every shade and variety of those colors: rose being probably the predominating color. The whole period of activity lasted about ten minuteafter which the corona expanded, lost its activity, and spread over the sky as a kind of milky haze Clouds soon afterward intervened and no further display was seen. During the active period (1) vertical intensity was greatly increased accompanied by a strong easterly deflection, and a decreain the horizontal force.

March 29, 1882, 3 a, m. to 7 a, m.—When first observed as daylight faded the arch had alread: passed the zenith but was very pale. The display was not a noticeable one, mostly appearing as hazy masses and partly formed bands or curtains of no great brilliance and was not observed after 7 a, m. The needles only slightly disturbed.

March 31, 1882, 4 a.m. to 8.15 a.m.—Began later than usual and was very faint. It was mostly confined to a single ray rising from the SE, towards the zenith and occasionally extended through to the NW. Sometimes none were to be seen for a short time, but the brightness of the moon may have hidden it. It was last seen after 8.15 a. m. (2.43 a. m. local), but the needles which had been steady during the greater part of the night became disturbed and read very irregularly for several hours afterwards.

Inril 3, 1882, 2 a. m. to 7 a. m.—Very pale and irregular shaped. Appeared only occasionally and mostly near the zenith. The cloudiness of the sky prevented it being observed. The moon being about the full and the clouds somewhat striated it was often difficult to say which was cloud and which aurora. Magnets somewhat disturbed.

April 4, 1882, 4 a. m. to 6 a. m.—First seen at 4 a. m. The brightness of twilight and the moon Leagy too great to permit of its being observed much sooner. First appeared as a faint narrow arch running from from N. to SE, with an elevation of about 20%. A few rays appeared and the arch assumed a curtain form, which was soon succeeded by the usual hazy condition of the sky. At 5 a.m. a similar curtain appeared for a short time, extending from NW, to SE, and elevated about 20 - above the horizon. At 6 a. m. a faint corona was formed with long, slender, and very faint rays converging towards zenith, but although displaying considerable motion no variety of olors was noticeable. It was only of few minutes' duration and was again succeeded by the hazy regulation of the sky. Clouds soon afterwards covered the sky so that nothing further could be . . . The needles were considerably agitated.

1,775, 1882, --- to --- Beginning or end not known in consequence of the cloudiness, egg at 5 a.m. (11.13 p. m. local of the 4th) the clouds around the zenith were all rendered largers as by transmitted light, the aurora behind them being apparently very bright. The magnets

were very much disturbed, the disturbance continuing until the afternoon.

17 6, 1882, 4 a. m. to ------The brightness of twilight prevents the beginning of displays being correctly ascertained, and when this one was first observed it was rather brilliant in the SE. at an elevation of 40°. While in this position, rays and streamers were rapidly developed which shot up towards the zenith while individually possessing a rapid swirling motion. An arched form combined with that of the curtain was then assumed, which extended across towards the NW., rising at the same time towards the zenith, the motion of translation being from W. to NE. Alter reaching the active condition it ceased and was succeeded by the usual hazy appearance of the sky. During the burst of activity the base of the whirling rays was often tinged with pink and rose; the prevailing color was yellow. During this time the magnets were much-disturbed, the vertical intensity on eastern declination being largely increased and the horizontal force decreased. Afterwards but little was seen, but as the cloudiness increased very rapidly it was impossible to say if any further bursts occurred. The needles were occasionally disturbed until everal hours after sunrise.

April 7, 1882, —— to ————The 7th was cloudy, but the magnetic disturbance was large.

Ipril 8, 1882, 4 a. m. to 7 a. m.—Began as a narrow band in the SE, stretching toward the N., which after a few minutes' quiescence became active and displayed considerable motion and a few traces of color, but very soon broke up into hazy patches. At 5 a, m, a narrow pale yellow arch extended across from NW, to SE, at an altitude of about 35% above the S, horizon. After remaining stationary for a short time it rose towards the zenith. Pale slender rays shot up from its eastern end, and several small patches of yellow light in a condition of rapid motion appeared along it. There was a slight approach to the coronal form, but all faded very rapidly, and at 5.20 no trace of it remained; no more appeared until about 7 a. m., when a faint ray appeared in the N. just outside of the line of twilight. There was a strong easterly deflection of the declination needle and an increase in the vertical intensity and decrease in horizontal force.

occurred, but only lasted about ten minutes. When first seen it was in and around the zenith, which was tilled with whiching vibrating rays. Flashes of green and rose appeared, but yellow, as usual, was the prevailing color. The magnets were considerably disturbed, the vertical intensity increasing, the horizontal force decreasing, and the deflection and netimes E, and sometimes W.

The night became cloudy and no more was seen.

April 10, 1882, 3 a. m. to 4 a. m.—The sky was hazy and partly covered with foggy stratus clouds, so that only the larger stars were visible, and then only near the zenith; besides, the twilight was so bright behind the clouds that it was sometimes very difficult to say which was twilight and which aurora. At 3 a. m. several pale white bands, probably auroral, extended from SE. to N. and to the E. of zenith. At 3.15 a. m. a pale yellow arch, certainly auroral, appeared in the SW, with an altitude of about 20°. At 4 a. m. there were luminous traces in the SE., but the clouds soon afterwards became too dense, and nothing more was seen. Needles slightly disturbed.

April 11, 1882, 4 a. m. to 6 a. m.—About the usual time as a faint ray running from SE to NW, with an altitude of about 30° above the SW, horizon. At 5 a. m. it had moved up to the zenith, where a kind of clongated corona was formed, the clongation being in direction of the length of the arch. This had been the general form of all the corona that have appeared. Elementated in direction of the arch and compressed at right angles to it. I may here remark that the autoral light is almost always something more, apparently, than simply so many areas of light of various shapes. It is composed of luminous medium which seems quite tangible, more like luminous cloud or dense vapor than anything else. Its distinctness of character and outline strongly tends to give it an appearance of nearness which I had never noticed any place else, but at the same time I have never been able to observe a case of where it appeared below any cloud strata. The clouds are often rendered luminous by it, but I am almost certain that in every case it was oy transmitted light. At 6 a. m. a faint streak was visible in the NE., but the twilight soon became too strong to permit its being visible.

April 12, 1882, 4 a. m. to 6 a. m.—Very faint, but interfered with by the increasing brightness of the twilight. At 4 a. m. there was a pale narrow arch running from the SE, horizon, S, of zenith, to NW, with an altitude of about 30°. After a short time this broke up into hazy patches which occasionally emitted a few rays, and appearing and disappearing from time to time until 6 a. m., after which the daylight was too bright to allow them to be seen. Magnets steady during the time display was visible, but some time after sunrise they were largely disturbed, the disturbance however, lasting only for a short time.

April 13, 1882, 5 a. m. — 3.—A few patches appeared in the SE, at 5 a. m., exhibiting considerable motion. The highest and brightest was immediately below a Boötis. They being immediately afterwards overcast, no more was seen. The needles were considerably disturbed for several hours after.

April 15, 1882, 5.50 a. m. to ——?.—Weather cloudy, but about 5.50 a. m. (12.30 a. m. local) auroral light appeared a little southward of zenith and apparently in rapid motion, the direction of motion being from S. to N. From the character of the light when in zenith there was a corona formed possessing a rapid gyratory motion. The magnets were largely disturbed, the horizontal force decreased, and vertical intensity being increased, and the easterly declination also increased; the needle swinging out of field, but afterwards there was a westerly deflection, but not so pronounced as the easterly. No more of the display was seen, but the needles continued unsteady for several hours afterwards.

April 16 and 17, 1882, magnetic storm.—On the 16th, about 1 p. m. (8 a. m. local) a very intense magnetic storm set in, which continued at intervals until about 9 a. m. of the 17th. The night was cloudy and no aurora was seen; the greatest disturbance, however, took place in the daytime. At first there was a strong E. deflection attended by a decrease in the horizontal and an increase in the vertical intensities, but about 7 p. m. there was a great change, the deflection changed to the W. so that the azimuth circle had to be moved several degrees to bring the needle into the field. An increase took place in horizontal force and an increase in the vertical intensity. Again, after a period of about five hours another change took place to the E., the vertical intensity increasing and the horizontal decreasing as usual, which conditions continued to the end.

April 20, 1882, 5 a. m. to —— ! .—At 5 a. m. auroral light was discernible a little S. of zenith The twilight was too bright to allow a distinct view to be had. The magnets were considerably disturbed. A very intense disturbance, however, took place some hours previously, commencing at 11 p. m. (5.43 p. m. local) of the 19th, and continuing more or less to 6 p. m. (12.43 p. m. local) of the 20th. The range of the various changes of declination amounted to over 10°, while that of the dipping needle amounted to 7°. The greatest deflection was westerly, but the E. was

As formerly, the westerly deflection was accompanied by an increase in horizontal force and a decrease in the vertical intensity, and the E. by an increase in the vertical intensity and a decrease in the horizontal force.

September 3, 1882, 4 a. m. to 4.30 a. m.—When first noticed at the 4 a. m. observation, the twilight was still bright in the N.—The aurora appeared in the constellation Auriga, as a small arched band rapidly shifting, extending in azimuth from about N. 70° E. to N. 90° E. (brightness 2) and showing faint tinges of red, green, and yellow. In fifteen minutes the whole aurora had risen and greatly extended, forming a number of sinuous shifting bands, color white brightness 2, extending from the NNE. horizon to SSW., passing through Ursa Major, Ursa Minor and Cygnus. At this time the needles were slightly agitated, while the earth currents showed no disturbance. Fifteen minutes later the aurora had disappeared, except a few scattered streaks, which continued faintly visible for an hour.

September 4, 1882, 4 a. m. to 4.05 a. m.—The sky was still quite light and overspread with chough hazy cirro-stratus cloud to dim the stars slightly. When noticed at the 4 a. m. observation the aurora occupied mostly the whole of the eastern sky, reaching the zenith. Color white; brightness 2; form utterly inconstant, shifting with the rapidity of lightning. In general the bands had a north and south direction and were inclined to be sinuous. The display was most prominent in the constellations Cassiopeia, Auriga, and Camelopardalis. In five minutes only a few pale streaks were faintly visible. The magnetic needles were slightly agitated.

September 5, 1882, 2 a. m. to 7.30 a. m.—The aurora appeared at 2 a. m., while the twilight was so bright that no stars were visible. It was then a slightly luminous band, white and unstable, extending from the SE, horizon to NW, about 10° W, of zenith; brightness 1 to 2. At 3 a.m. the bands were broad and more numerous, sinuous and shifting, running from N. to SE. through Ursa Major, Ursa Minor, Cassiopeia, and Pegasus; brightness 2; color white, with several paler arched bands in SW., one of which at 3.15 had reached the brightness of 3, with a bright yellow color, while the main aurora had somewhat faded. The magnetic needles were slightly agitated. At 1 a. m. the aurora overhead had almost wholly disappeared, while a new band had appeared in Taurus near the NE, horizon, extending into Gemini. This band was yellow, sinuous, and rapidly changing in form, approaching, however, the curtain type. Altitude about 20°; brightness 3, brightest in Hyades. It was replaced at 4.15 by a comparatively steady pale (1) arch with streamers, reaching its greatest altitude close above a Geminorum, extending in azimuth about 40°. At 5 a.m. a sinuous band with streamers was observed in Canis Minor, stretching into Hydra close to eastern horizon (brightness 2). At 6 a.m. there was an extensive sinuous band, approaching the curtain form, mostly in Hydra and Virgo. This showed violet color in Hydra, where it was brightest (5; elsewhere 2). The whole aurora was exceedingly changeable and shifting, ending with a long sinuous band, pale (brightness 1), running through Ophiuchus, Corona Borcalis, and Canes Venatici.

Neptember 6, 1882, 3.30 a. m. to 6 a. m.—As early as 3.30 a. m. streaks of auroral light were visible through the fog, and at 4 a. m. a definite aurora in the form of a pale band stretched across from the southern horizon to the W. of the zenith, starting in Aries and passing through Triangulum, Andromeda, Lacerta, and Cygnus, and ending near a Lyra. This band moved towards the zenith, fading and reappearing, and at 4.05 passed through Cassiopeia. The fog cleared as the night grew darker, and the aurora appeared as bright horizontal bands near Aquila. At 5 a. m. a bright (2 to 3) sinuous arched band with streamers ran along the western horizon, from Libra, through Hercules and Vulpecula, to Pegasus. At 5.30 a brilliant whirl in the S. sent up streaming bands, one through Cassiopeia across the zenith, ending in Boötes: a second through Andromeda and Cepheus, ending in Corona Borealis; a third through Pisces to Aquila. The aurora ended with a single sinuous band running up through Taurus and Auriga from the southern horizon and reaching to Ursa Major.

September 12, 1882, 4.17 a. m. to 4.50 a. m.—The clouds which had covered the sky during all the evening cleared off near the zenith at 4 a. m., and at 4.17 a white, hazy but well defined rather narrow band, shifting its position, appeared stretching from NE. to SW., passing through Ursa Major, Ursa Minor close to the zenith, and Cepheus, ending in Cygnus (brightness 1). The mag-

netic declination and vertical force were but little affected, while the horizontal force was very greatly increased. The band was invisible at 4.50, and the sky soon clouded over.

Neptember 15, 1882, 2 a. m. to 7 a. m.—As early as 1 a. m., while the twilight was still bright, pale whitish bands were to be seen crossing the sky from the N. to SE. These at 2 a. m. had developed into an aurora, brightness as high as 2, beginning near the SE, horizon in Pegasus, where it was brightest, narrow, and of a yellow color. As it approached the zenith in the form of a sinnous shifting band it became somewhat paler, and stretched in width from Cassiopeia to Cygnus, narrowing again and ending in the twilight just below Ursa Major. Most of the aurora was white in color. At 3 a. m. a broad arch (brightness 3) passed from the SE, horizon, begin ning in Pisces and running through Pegasus, Andromeda, Lacerta, Draco, and the tail of the Dipper, and ending in Canes Venatici. Slight magnetic disturbance. At 4 a. m. the sky was hazy and no aurora visible, and at 5 a. m. the sky was clouded over. At 6 a. m. pale bands (brightness 1) stretched across the sky from Taurus and Aries in the SE, through Ursa Major near the zenith, ending in Corona Borealis. At 7 a. m. there was one pale band (brightness 1) in SE, occupying the constellations Gemini and Leo, and another similar but smaller band low in W., in Hercules and Vulpecula.

Neptember 25, 1882, 2.17 a. m. to ———. Up to 2 a. m. the sky was completely covered by heavy stratus clouds, but at 2.17 these broke away near the zenith, exposing several horseshoe-shaped concentric sinuous arches rising from the N. The apex of the brightest arch was near Polaris, and other paler bands apparently forming part of similar arches were visible in Cassiopeia. The near arch had a brightness of 2, the others about 1, and all appeared quite unstable. The sky continued much covered with rapidly moving clouds and the aurora was only visible at intervals through openings between them. At 3.17 a.m., three pale (0 to 1), motionless, slightly arched horizontal bands were visible in the N., in the constellation Canes Venatici. At 4 a. m. the sky was much clearer, and a band of streamers pointing towards zenith flashed across the sky from NW, to S. on an arched course at an altitude of about 45°. The motion of translation from N. to S. was very rapid and accompanied by a rapid vibration from S. to N., and rice versa. The brightest part of the display was tinged with red and yellow, and reached a brightness of 3. At 4.17 there was a a small patch of aurora reaching a brightness of 3 in the constellation Aries on the SE, horizon, This had the form of a vertical sinuous streak, and showed red and yellow colors, fading rapidly and shifting and twisting. At the same time the clouds in the SW, were illuminated with a bright greenish auroral glow. After this the sky became completely overcast. A magnetic disturbance began in the afternoon and continued all night (local time), the declination varying through a range of 1° 38′, the horizontal force .424 and the vertical force .055.

September 26, 1882, 3 a.m. to 6 a.m.—At 3 a.m. the clouds had broken away so as to leave the northern sky clear, and then there appeared three horizontal curtains taking in about 452 of azimuth from the N. to NE., the altitude of the highest being about 30°. They occupied for the most part the constellation Leo, though with the twilight and moonlight it was impossible to see the stars distinctly. Their brightness was 3, the lower edge of each curtain colored bright rose, then yellow, and finally pale yellowish green. There was a rapid lateral vibration and the whole had completely faded in about five minutes, leaving only a few bright streaks, and a new curtain then formed a little farther to the E. At 4 a. m. there were small patches in Beötes and a quiet narrow arch, greenish with a faint rose tinge on lower edge, brightness 3, running from near Arcturus, on the northern horizon between Castor and Pollux, and ending in the clouds near the Hyades. This had entirely faded at 4.17, when a broad sinuous band rapidly developed from the N. running from near Arcturus, through Ursa Major, Ursa Minor, Cassiopeia, and Taurus, toward the SE, horizon. This moved rapidly towards the W., reaching Cygnus in two minutes and quickly fading there, the southeast end in the meanwhile having broken into irregular streaks. At 5 a, m, the aurora was faint and pale yellowish green, in the form of two streaks running through Leo, Gemini and Cancer. At 6 a. m. a broad bright sinuous band crossed the sky from N. to S., passing through the zenith and moving rapidly toward the E. Brightness 3. The sky then became cloudy. A large magnetic disturbance lasted through the aurora, with decrease of all three elements.

September 30, 1882, 1.17 a. m. to 4.30 a. m.—The aurora was fully developed at 1.17 a. m., when

the clouds broke away sufficiently to allow it to be visible. It was very pale (0 to 1) and in the form of a sheaf of narrow, quiescent, white, hazy bands, stretching neross the sky in the NE. from a point near Arcturus in the N. through Ursa Major, Auriga, and Perseus. At 2.17 the clouds were merely open enough to show traces of aurora in the form of pale streaks in Ursa Major, in the N. and overhead. At 3 a. m. the sky was quite clear, and only pale, quiet, white bands, radiating from a point in Boötes near the NW. horizon and converging to a point in Taurus near the SE. horizon, covered nearly the whole sky. The light was much dimmed by the full moon. At 3.17 and at 4 the aurora was essentially unchanged, though some bands faded and others were formed, and the whole was much obscured by haze at 4. At 4.17 there was rapidly developed near the southern horizon, dimly visible through the haze, a twisted horizontal band with a rapid aution and indications of color which must have had a brightness of 3. The stars near it were invesible. After this the aurora faded, none being observed at 5 a. m.

October 8, 1882, — to 8.30 a.m.—The sky was alternately clear and overcast during the early part of the night, but no aurora was noticed until 4.45 a.m., when bright bands, white and motionless, crossed the zenith from N. to S. The sky soon clouded and no aurora was observed at the 5 a.m. observation. At 6 a.m. a quiet yellowish band had passed up from Orion on the SE, horizon nearly to Cassiopeia, then declining towards Andromeda (brightness about 1). At 7 a.m. a small yellowish patch in Taurus (brightness about 1) was all the aurora visible. At 8 a.m. another pale yellowish green arch stretched from the N. to the E. point of the horizon, reaching an altitude of about 20°. At 8.30, though the sky was perfectly bright and clear, no aurora was to be seen. Neither the galvanometers nor magnetic instruments indicated any disturbance.

October 10, 1882, 2 a, m, to 6 a, m.—Light snow fell during most of the night, but the sky cleared at intervals. At 2 a, m, traces of aurora were visible through the hazy clouds, in the form of a quiet band running across from N, to SE, near the zenith. At 4 a, m, the sky cleared 50, showing a bright patch in Aries near the S, horizon with some horizontal bands in SW,, brightness 2 to 3. At 4.17 bands, brightness 2, beginning in Lyra and passing through Cygnus. There was no rapid motion or vibration, only a slow drifting and breaking of the bands, which quickly faded and new ones developing, especially one somewhat twisted and undulating from Lyra, through Cygnus and Andromeda, to Aries on the S, horizon. At 5 a, m, the arch was in the SW,, running from W, to S, yellowish in color and vibrating rapidly, also twisting up and down vertically. At 6 a, m, a bright band passed from NE, to SE, with a rapid lengthwise vibratory motion, several times parting in the middle. The clouds then became too thick for the aurora to be seen. A considerable magnetic disturbance commenced at 6 a m., continuing twelve hours.

October 11, 1882, 3 \(\epsilon\), m, to 4.30 \(\alpha\), m.—Light snow was falling up to 3 \(\alpha\), m, when the hazy nimbus cloud broke rapidly away, disclosing a white hazy band (brightness 0 to 1), quiet, stretching across from Herenles in the N., through Cygnus, Lyra, Cassiopeia, and Andromeda, ending in clouds near Aries in SE. This was a little brighter at the SE, end at 3.47, when the horizon again thickened up. At 4 \(\alpha\), m, the sky was again clear, but the aurora had faded to a pale band on the edge of the clouds in the SW,, and in 10 minutes there was only a vague luminosity in the E, and SW. During the rest of the night the sky was cloudy.

October 12, 1882, 12 midnight, October 11, to 9 a.m.—The sky cleared suddenly, disclosing an arch in the NE, with its crown in Andromeda, and its extremities buried in the clouds. Its brighters swas 2, and it continued to rise and spread till, at 1 a.m., a broad, bright simous band ran from the N. to SE. horizon, occupying mostly the constellations Corona Berenices, Usar Major, Camelopardalis, Persens, and Aries. Until 1.17 the only change was a slow spreading and undulation, maying from the zenith eastward and slowly back again. The N. and SE, ends remained quiet, the SE, end the brightest, while the center changed into one, two, and three bands of vertical streamers and back again to wavy bands. The brightness of the band was from 3 to 4, and the ed, a were tinged with rose and green. There was a magnetic disturbance, with increased decliration and decreased horizontal force. At 2 a.m. there was merely a quiet atch, with streamers

running from Leo, on the N. horizon, reaching its greatest height above a Geminorum, passing through the Hyades and ending at a point below these on the SE, horizon. This had faded almost completely at 2.17, and a few pale streaks crossed the zenith from N. to SE. The aurora was similar in character to this at 3, but the arch passed between Castor and Pollux. The magnetic needles had in the mean time returned to their normal readings since the disturbance at 1 a, m. At 4 a. m. a broad hazy band stretched from Boötes close to zenith through Cygnus and Lyra to the SE, in Aries. At 5.17 this began to spread and break up, rapid gyratory motion commencing in Cassiopeia, and spreading in a few minutes all over the sky except the NE. There was an indescribable confusion of smoke-like wreaths, whirls, curtains, and shooting streamers. The motion was all gyratory, or motion of translation, very rapid and in no given direction. A special center of gyration, whirling from N. to S., developed rapidly and as rapidly disappeared in Perseus. The display reached a brightness of 3 to 4, and showed rather faint colors-green, rose, and peach-blessom. In about 5 minutes all became suddenly pale and quiet, but showed sign of breaking out again. At 5 a. m. a pale yellowish band ran from N, to SE, horizon, reaching an altitude of about 40°, quiescent (brightness 1 to 2). At 6 a. m. three arches were observed forming a triangle (brightness 1 to 2). At 7 a.m., one broad band crossed the zenith from NW, to ESE, (brightness 1 to 2). No aurora was observed at 8, but at 9 a, m, a pale, arched band (brightness 0 to 1) was observed low in the SW. (26° altitude), running from Canis Minor in the SE, to the lower part of Taurus, through Orion. This was the end of the aurora, fading before daybreak.

October 13, 1882, 2 a. m. to 9.50 a. m.—The haze which overspread the sky was quite thin at 2 a. m., and a hazy, quiet, arched, and slightly simuous band, white in color, passed from a point in Taurus on the SE, horizon to a point in Coma Berenices on the northern. The arch slowly rose; the crown being just above Castor and Pollux at 2, close to Capella at 2.10, and when last observed at 2.17 just above Capella and still rising, the band spreading slightly (brightness 1, rising to 2 at the N, end at 2.10). At 3 and 4 this aurora was replaced by a few vague traces. Up to 9 a. m. no aurora was observed, the weather being hazy. At that time a white, quiet arch was observed passing from the ESE, through Canis Minor and Taurus to the WNW., about 2° in breadth, altitude 50° brightness 2. At 9.20 there was a second arch about 2° above and parallel to the first, not continuous, but consisting of a series of luminous patches resembling long-drawn cirrus clouds, motionless, and similar in brightness to the first arch. At 9.40 a. m. the western extremity of the first and broader arch was observed to slowly change form until it resembled the folds of a curtain, when the whole slowly drifted southward and disappeared about 9.50 a. m.

October 14, 1882, 2 a. m. to 9.46 a. m.—At 2 a. m. a narrow and barely perceptible band, perfeetly straight, ran from the SE, horizon through Andromeda nearly to the zenith, paler than the Milky Way. This was perceptibly brighter at 2.20, and there was a pale glow along the horizon in the NE. At 3 this had developed into a slightly sinuous band running from the SE, horizon through Pegasus across the sky through Cygnus and Lyra to the NNW. (brightness 1). Also a pale arched band, much curled at the east end, from Taurus through Auriga, running close to the Dipper and fading in the N. The main arch drifted to the SW, slowly and beamed brighter (1 to 2), dividing longitudinally into three bands, while the eastern aurora faded. At 4 a. m. three bands crossed the southwestern sky, united at the horizon, and spreading at the center from the SE, to NW. Altitude about 20°, breadth at broadest part 10°, brightness 2 to 3, occupying constellations Pegasus, Delphinus, Aquila, and Ophiuchus. Upper band somewhat broken into streamers, especially at SE, end. This was all fading rapidly at 4.20. At 5, two luminous yellowish bands (brigh(ness 2 to 3), passed from SW, to NW, through Delphinus and Serpens. At 6, one arch, with bright streamers moving from W. to E. and vibrating, passed from Orion through Ursa Major and ended in Boötes (brightness 3). At 7, a band (brightness 2 to 3) ran from Cancer through Ursa Minor. At 8, a band with bright streamers at the north crossed the zenith from NNW, to SSE. (brightness 3 to 4). The whole moved slowly southward. At 9, a broad, broken, vaporous arch from N. to S. crossed the zenith. This changed its form a little but not its position, until it faded about 9.46 (brightness 0 to 1).

October 15, 1882, 12.5 a.m. to 10 a.m.—The aurora commenced as a narrow pale band, beginning near the Pleiades and running along the horizon fading in Gemini. This was a little brighter at 12.20. At 1.20 it extended across the zenith from Aries on the SE, horizon to Leo on the

rum, passing faded almost rora was simhe magnetic ice at la. m. and Lyra to commencing There was an camers. The n. A special eared in Pereen, rose, and sign of breakg an altitude forming a tri-ESE. (brightss 0 to 1) was

northern, consisting of several sinuous bands, shifting and somewhat wavy, occupying Taurus, Persons, Cassiopeia, Ursa Minor, and Ursa Major (brightness 3 to 4), color white, with tinges of green and yellow; motion undulating and rather rapid. At 2 a. m. the aurora passed through Boötes to Leo Minor and to Gemini. At 3, two bands rose together from Serpens near the horizon, one passing through Pegasus and Cygnus, and the other through Andromeda and Lacerta, while an arched band crossed the eastern sky from Boötes in the N. to Taurus in the SE., massing through Ursa Major. Both sets of aurora were quiet and yellowish (brightness 3 to 4). At 4, a broad, quiet, white band (brightness 2) crossed the zenith from Leo Minor through Ursa Major, Ursa Minor, and Cygnus, ending in Sagitta. At 5, three bands (brightness 3) crossed the zenith, occupying Lyra, Cygnus, Cassiopeia, Pegasus, and Taurus, with a few bright streamers in the NNW. At 6 a. m. an arch (brightness 2) ran from Boötes through Canes Venatici and Lynx, ended in Gemini, while a double arch (brightness 0 to 1) lay about 10° above the SW, horizon, running from NNW, to ESE. This arch was still in the same position at 8 and had become a single band at 10. At 7 there were pale patches of yellowish light in the NNE, near the horizon. Between 9 and 10 the arch in the SW, was bright, quiet, and well defined, with tremulous streamers (brightness 3 to 4), colors bright green, yellow, and rose. Extensive magnetic disturbance.

October 16, 1882, 12.40 a. m. to 4 a. m .- Streamers flashed up in the E., forming a low arch from Taurus in the SE, to Leo in the N., with the crown in Gemini (brightness 1). At 1 a. m. there was a definite narrow arched band with one end in Leo in the N, and the other in the lower part of Aries in the SE., with the highest part in Auriga and Perseus. From the northern end numerous long quiet streamers ran up as high as Ursa Major (brightness 1). The whole was rising slowly when last observed at 1.20. From 2 to 2.20 the aurora was in the form of a broad band, narrow at the ends and spreading, and crossed the zenith from Pisces in the SE., near the horizon, to a point in Boötes, near the northern horizon. It occupied chiefly the constellations Andromeda, Perseus, Cassiopeia, Ursa Minor, and the western portion of Ursa Major. The band was slightly sinuous, and by imperceptible degrees changed its shape without changing its position, breaking into several bands, and consolidating itself into one again, its brightness increasing from 1 to 2. An eastern band joining this at the ends passing through Auriga was well defined at 2.17, and almost wholly gone at 2.20. At 3 the aurora was in the same place, but had grown paler and more diffused, while at 3.15 the eastern band was again well developed and the aurora was spreading westward as far as Cygnus. At 4 the sky was so hazy that only the brightest stars were visible, but through the haze twisted bands of aurora in rapid motion were to be seen. After this the cloud thickened up and no more aurora was observed. A magnetic disturbance commenced at 3 and lasted till 7 a.m., with decrease of horizontal force from .530 to .215, while the declination increased 60 07', the vertical force being but slightly affected.

October 17, 1882, 11 p. m., October 16, to 10 a. m.—Before the stars were definitely visible a twisted band of aurora was observed across the zenith from the NNW, to the SE, (brightness 1). At 2.17 there were three bands nearly overhead, running from NW, to SE, through Ursa Major, Ursa Minor, Cepheus, Canes Venatici, and Boötes. These bands were white, tinged with greenish (brightness 2), with undulating motion, the ends shifting and disappearing. The magnets were slightly disturbed. At 1 a. m. there were two small horizontal curtains in Taurus, from whose western end rose a broad, spreading, sinuous band across the zenith to Boötes in the N., occupying Andromeda, part of Cassiopeia, and Ursa Major, spreading W. into Cygnus and Lyra (brightness 2), with slight wavy motion. This was breaking up and paler at 1.10, and had become a single twisted band, with a tendency to divide lengthwise at 1.17. At 2 the aurora was in essentially the same position, but the western part was brighter, and had sunk lower in the SW., passing through 3 Cygni and Vulpecula. This portion reached a brightness of 3 at 2.17, while the rest had paled considerably. At 3 there was a twisted mass of light in Taurus, and a narrow bright (3) band running along the SW, horizon through Aquila, extending about 90° in azimuth. At 3.17 a brilliant dispiay began, which was observed up to 3.25. The aurora developed from the SW, up to the zenith and a little past it with great rapidity in the form of whirling, circling bands and smoke-like wreaths, mingled with pale streamers, which latter formed an imperfect corona at 3.20 in Cassiopeia at the zenith, which disappeared quickly. The motion was very rapid, and the light reached a brightness of 3 to 4. The light was mostly yellowish-white, but tinged on the lower edge with

H. Ex. 41-49

greenish and rose. The magnets were violently disturbed, with great decrease of borizontal force, At 4 a. m. three bands ran along the SW. from Orion to Aquila at an altitude of about 25°. These reached a brightness of 3 at 4.15, and then quickly paled, while the aurora developed from Orion and spread over the eastern sky in broad, sinuous, undulating bands (brightness 1 to 2), which formed a very transient, imperfect corona. This aurora was brightest in Ursa Major, and spread over the whole sky at 4.20. The motion was comparatively slow, and the magnets less disturbed. At 5 there were two quiet greenish bands (brightness 2), one in the NE, through Gemini, Leo Minor, and Coma Berenices, and the other in NW, from Boötes through Hereules and Aquila. At 6 a pale broad band ran from the western to the southern horizon, and at 7 a similar band in the NE, ran from Gemini through Ursa Major and ended in Boötes. At 8 there were numerous streaks (brightness 2 to 3) in the NE, moving rapidly westward. No aurora was observed at 9, but at 10 there were traces of a pale arch extending from the NNW, to ESE, at an elevation of about 12° above the southern horizon. The extremities were lost in the baze and cloud which obscured the horizon.

October 21, 1882, 7 a. m. to 8 a. m.—Up to and during the 6 o'clock a. m. observation the sky was clouded over and it was snowing; but at 7 a. m. it was clear, and a stationary yellowish white band of aurora was observed running from Hercules in the WNW, through Pegasus to Taurus in the SSE. At the WNW, end there were vertical streamers, vibrating upwards rapidly (brightness 2 to 3). At 8 a greenish band without motion crossed the zenith from Boötes through Ursa Minor to Triangulum (brightness 2 to 3), while at 9 a. m. the same band, somewhat paler (2), passed beyond Triangulum into the haze on the eastern sky. Magnetic instruments showed no signs of disturbance.

October 22 and 23, 1882, 10.30 p. m. to 10.20 a.m.—As soon as it was dark enough for an aurora to be seen, a slightly sinuous, narrow, hazy band was observed crossing the zenith from N, to the SE., passing straight up through the middle of the Dipper. In the twilight it appeared a pale rosy color, and a slight wavy motion was observed (brightness 0 to 1). Next observed at 11.15 in the shape of a broad, waving band from the NNW, to SE, not reaching the horizon at either end, passing through Ursa Major, Draco, and Cygnus (brightness 1), color yellowish. At 12.15 a.m. October 23 it was a narrow arch from the NW, to SSE, through Vulpecula, Delphinus, Cygnus, and Lyra to Boötes, with little or no motion (brightness 1). At 1 a. m. a low arch (brightness 2), somewhat tinged with yellow, lay in the SW., taking in about 40° in azimuth and reaching an altitude of about 20° near a Aquilæ. All the stars on the SW, horizon were obscured by the bright moonlight. This arch had not changed its position when last noticed at 1.20, while at 1.10 an additional hazy, wavy 1 and had developed in the NE., running from Taurus in the SE, through Auriga to Coma Berenices in the N. (brightness 1). At 2 a. m. the starting point of the aurora was in Taurus, near the SE, horizon. From this ran a band of streamers to the NNW, through Aries, Pegasus, highest in Cygnus, near \( \beta \) Cygni, through Lyra and Hercules round to Bo\( \beta \) to 21, and also bands (brightness 1) across zenith passing through Cassiopeia. From 2.10 to 2.20 the western band became brighter, with considerable motion, and gradually faded, while the eastern bands, still pale, spread eastward into Auriga, developing a bright patch in Canes Venatici. The magnets were slightly disturbed. At 3 a, m, the western streamers were replaced by a pale (0 to 1) band, and another band couldly pale crossed the zenith from the same starting point. At 3.10 to 4 an additional sinuous band (1 to 2) developed in the E, from Orion just rising in the SE, through Gemini, Leo Minor, and Canes Venatici to a point in Boötes, now just above the northern horizon.

From 4 to 4.10 there was an extensive display, which would have been brilliant had it not been for the moonlight. Starting from Orion it spread into Taurus, Aries, and Auriga in the shape of twisted forks, one streak crossing the zenith to NNW., with a band nearly in the position of the western band seen at last observation. This latter band had risen about 10° at 4.10. No rapid motion was observed (brightness 2 to 3). The whole was fading rapidly at 4.17. There was a great magnetic disturbance, the horizontal force falling too low to be read, and the declination rising. At 5 a. m. only one pale (0 to 1) band was visible running from Leo to U1sa Major, resembling hazy cirrus cloud. At 6 a. m. there was a pale arch over the NE, horizon, and at 8 a. m. another similar arch (brightness about 1). At 9 and 10 a. m. there was simply a trace of aurora in the form of an arch closely resembling the twilight curve, spanning the southern horizon at an

altitude of about 40°, the extremities hidden in the baze which obscured the horizon. This had wholly disappeared at about 10.20 a. m.

October 27, 1882, 1 a. m. to 4 a. m.—The clouds which had covered the sky broke away about ! a. m., having a few patches of fleecy circus stratus clouds hiding the stars in the SE. At the 1 a. m, observation two hazy, narrow, sinuous bands crossed the zenith from this bank of clouds, ending near Arcturus in the NNW., about 15° above the horizon, passing through Cassioneia, Cepheus, and Draco. At 1.17 the top of the arch had drifted west to Cygnus and Lyra, the ends remaining axed, while the arch itself showed a tendency to split lengthwise (brightness 1); brightest in Boötes. where it had a faint ruddy tinge. There was a slight magnetic disturbance. At 2 a. m. an arched narrow band (brightness 2) stretched from a point in Serpeus about 10° above the NW, horizon to the bank of clouds in the SSE,, reaching an altitude of about 30° near a Aquilae. There was a faint suggestion of green and rose color at the northern end. At 2.10 to 2.19 the band faded slightly, and at 2.17 the crown rose about 2°, while at the same time there were also faint traces of a band in the position of the one observed at 1 a.m. From 3 to 3.17 there was a broad aurora running from a point in Boötes W. of Arcturus just above the northern horizon up through Ursa Major, Ursa Minor, and Perseus, ending in the clouds near Taurus (brightness 1 to 2). It consisted of broad, hazy, waving bands and twisted streaks fading and reappearing quickly, with slight motion, shifting rather to the westward. At 2.10 there were whirls approaching the curtain shape in Canes Venatici, and a low ill-defined arch in the NE, in Leo Minor, and at 2.17 also a faint band through Cygnus in the W. The magnetic disturbance increased in violence, all the elements being much diminished. From 4 a. m. onwards the sky was obscured by thin clouds. During the whole time the aurora was visible its brightness was much dimmed by the exceedingly bright moonlight.

October 27 and 28, 1882, 10.30 p. m. to 1.17 a. m.—As soon as it was dark enough for the aurora to show, a bright patch with bright streamers was observed in the SE., about 20° above the horizon. At 11.13 the aurora was in the form of a hazy arch, with its crown passing through Cygnus and Lyra, and its extremities hidden in the haze NW, and SE. At 12.13 the sky was so hazy and the moonlight so brilliant that the position of the aurora among the stars could not be definitely traced. It had the form of a faint arch of hazy light. The crown of the arch bore SW, at an altitude of about 30°. Extremities bore SE, and W, by N. At 1 a. m. only the brightest stars were visible through the haze. One broad band made up of transverse streamers, moving rapidly westward with quick undulations from N, to S., crossed the zenith from the N, ending in the clouds in the SE. Several paler secondary bands W, of the main band. The whole aurora was paler and much broken at 1.10. At 1.17 it had almost wholly faded, but quickly reappeared in the N, in the form of curled streaks, covering a large extent of sky. A large magnetic disturbance commenced at 10 p. m., continuing all night. The horizontal force ranged through .517, the declination through 2° 54′, and the vertical force through .088. At 2 a. m. the sky was clouded, and no more aurora was seen.

October 29, 1882, 5 a.m. to 11.30 a.m.—Up to 5 a.m. the sky was covered by thin, patchy, stratus clouds, through which the moon shone; after this the sky cleared off. Soon after dusk faint traces of aurora were seen through the clouds. At 2.13 a.m. a bright streak showed through the clouds in the NNE, the base about 20° above the horizon and running up towards the zenith. At 3 to 3.10 the sky was clear enough near the zenith to expose a band crossing from the N. when it was visible through the clouds to the SE. It could be seen to pass through Lyra and Cassiopeia. At 5 a.m. a band, partly covered with clouds, ran from Boötes through Draco, ending in Andromeda. It was pale and hazy (brightness 0 to 1), and moved slowly to the W. No more aurora was visible till 9 a.m., when a band passed from Ursa Major through Camelopardalis, ending in Cassiopeia (brightness 1). At 10 a.m. a band ran from Leo Minor to Perseus, passing through a Aurigæ (brightness 2). At 11 a.m. a patch was visible in Gemini. A violent magnetic disturbance commenced at 3 a.m., lasting all night. The horizontal force fell too low to be read.

November 2, 1882, 12.30 a. m. to 4 a. m.—From 12.30 to 12.45 a pale, glowing segment, resembling the twilight curve, was discernible in the NE., extending from N. to SE., and reaching an altitude of about 30° in the NE.—It was very pale, a little brighter in the N., and continued indistinctly visible until 3, when it developed into two or three definite, but wayy, pale (0 to 1) bands crossing

November 3, 1882, 12.17 a, m, to 8 a, m,—Streamers of a slightly vellowish tinge (brightness) to 2) shot up all round the horizon, being brightest in the NW, and SE. At 1 n. m. they had arranged themselves in the form of an arch of streamers (brightness 1), running from Taurus in the ESE, through Auriga to Ursa Major in the N. This had faded a good deal at 1.10 and was replaced by a pale arched band at 1.17. At 2 there was a vertical streak in the N. in Boötes. running up from near the horizon into Draco, and a few additional streamers were to be seen in Ursa Major at 2.10. This had faded at 2.17 and there appeared a pale arched band in Leo in the NE. At 3 a. m. there was a pale glow in the S. and SW., and at 3.10 a definite band (brightness 1) from Aries in the SE, up through Perseus and Andromeda to Cassiopeia near the zenith. At 3.17 there were merely patches of pale glow in the N. and NE. At 4 a. m. these bands (brightness 1 to 2) ran from the SE, to the NNW,, not reaching the northern horizon (brightest in the SE.); one (the brightest) from Orion through Taurus, Perseus, Cassiopeia, Cygnus, and Lyra; a second (paler) through Aries and Andromeda and just above a Aquila; and the third (palest) close to the horizon. These bands were in essentially the same position and a little brighter at 4.10, but had faded to 0 to 1 at 4.17. At 5 a, m. there was a pale band (0 to 1) in the NE, through Leo and Gemini. At 7 a. m. two bands (brightness 1) of a slightly greenish tinge crossed the zenith from Serpens to Cassioneia and Camelonardalis. At S a, m, there was an arch of very pale light over the SE, horizon, and after this no more aurora was observed.

November 4, 1882, 4,10 a, m. to 9.30 a, m.—The sky was covered with rather thin hazy stratus clouds which cleared away more or less at intervals. At 4.10 a.m. there was a quiet arch (brightness 1) visible through the clouds in the NE. There were no stars visible near this, so it could not be charted. The crown bore NE, altitude about 30°, and the extremities NNE, and ENE, altitude about 10°. This was wholly observed at 4.17. At 9 a. m. the sky was clear and a faint arch (brightness 0 to 1), extending from NNW, to ENE, with an altitude of about 30°, was observed lasting until 9.30.

November 5, 1882, 1 a, m, to 6 a, m.—At 1 a, m, there was an arched bank of clouds in the NE. on the horizon, and above this a pale steady glow gradually fading into the starlight. At 2 a.m. this glow had faded, but at 2.10 a broad definite band (brightness 1) crossed the NE, sky, white and motionless, from a point in Orion near the ESE, horizon, reaching its greatest height at Castor and Pollux in Gemini and ended in the upper part of Leo in the NNE. Its altitude was about 5° less at 2.17. Clouds and haze obscured the aurora till 6 a, m when an arched band was observed, with essentially the same bearing, running from Orion through Auriga to Ursa Major (brightness 2) and color slightly greenish, sometimes varying slightly in color and brightness especially in the SE., where a few streamers were observed. No more aurora seen.

November 6, 1882, 7 a. m. to 7.15 a. m .- Up to 7 a. m. the sky was not clear enough to allow any aurora to be seen. An arch of pale yellowish green was then visible through the haze, running from Orion to Leo through Gemini (brightness 0 to 1). This was invisible at 7.15 and no

more was observed.

November 7, 1882, 4.17 a, m. to 11.20 a, m,—The weather was stormy and the clouds thick during the early part of the night. At 4.17 a, m. an arched band was visible through the clouds in the SW, at an altitude of about 40°, quickly disappearing, while a similar streak in the NW. moved rapidly towards the zenith. No stars were visible at this time. There was a slight magnetic disturbance, with a decrease of horizontal force and declination and an increase of vertical force. The earth currents were notably increased in strength. At 11 a.m. the sky was comparatively clear, and a band was observed stretching from Andromeda through Ursa Minor to Canes Venatici, characterized by frequent flashes from W. to E. and a rapid vibratory motion. At 11.10 a. m. it had moved further toward the NE, and extending from N, to E, through Cygnus, Draco, and Boötes. It now consisted of a broad regular arch formed of streamers about 10° in length and perpendicular to the magnetic meridian. The streamers were agitated by a vibratory motion and a motion of translation to the E. (brightness 2). The aurora disappeared about 11.20 a.m.

Norember 8, 1882, 4 a. m. to 10:35 a. m.—During the early part of the night the sky was covered with thick clouds, but at 4 a. m. these had thinned away sufficiently to allow a few of the brightest stars to be seen, and broad bands of aurora, apparently in rapid motion, were observed crossing the zenith from the NNW. to ESE, spreading out at the zenith to a trail some 10° in width. No more aurora was observed until 9.10 a. m., when it appeared for about twenty minutes in the form of a quiescent faint band across the zenith from NW. to SE, with the extremities lost in the haze. At 10.10 a. m. a band (brightness 0 to 1) encircled the entire horizon, about 10° in breadth, and resting on a dark band of uncertain character (apparently hazy and stratus cloud) of about the same breadth. At the same time a second similar band formed an arch intersecting the first in the SE, and N., with its crown at an altitude of about 45°. At about 10.35 the sky clouded over and no more aurora was observed. A magnetic disturbance commenced about 4, chiefly affecting the horizontal force, which was largely decreased.

November 9, 1882, 12:30 a. m. to 7:30 a. m.—At midnight no aurora was observed, but at 1 it was already well developed in the form of a brilliant zone (2) from a point in Taurus in the ESE. horizon into Ursa Major and Leo Minor on the N. In the NE, it did not reach lower than Gemini, but extended also into Auriga. The zone consisted of three or four bands changing rapidly, but not moving fast, forming sometimes whorls and streamers, and had spread into Perseus and Andromeda at 1.10. At 1.17 it had faded a good deal, while two streamers started up in the N. and ESE., meeting across the zenith, while a large whorl formed in Canes Venatici. At 2 a. m. the zone was still broader and contracted at the horizon, ran from Hercules in the N. to Taurus in the SE, mostly west of the zenith, occupying Pegasus, Cassiopeia, Cygnus, and Lyra, drifting westward with rapid shooting and circling motion from SE, to NW. It had faded a little at 2.10. and was quiet, while quiet glowing banks of light replaced the 1 o'clock aurora. At 2.17 the western aurora had almost wholly faded, and the eastern developed into a regular arch, which test its regularity in a few minutes. At 3 a.m. the eastern zone had developed again from Orion in ESE, to Bootes in NNW., narrowing at the horizon, in the middle stretching from Gemini up to Ursa Minor (brightness 3), made up of sinuous bands, sometimes narrow, sometimes broad, with some longitudinal motion from N. to S., spreading a little towards the W., and not so bright at 3.17. At 4 there was a similar broad band or zone, but quiescent (2 to 3) from a point in Monoceros in the ESE, through Orion, Taurus, Pegasus, Cygnus, and Lyra, to a point in Ophiuchus near the NNW, horizon, also spreading eastward in paler bands to Ursa Major, growing paler at 4.17. At 5 a. m. two parallel bands 4° to 5° apart crossed the zenith from Taurus, through Persens and Cassiopeia, to Corona (brightness 2), drifting slowly S., with a rapid waving motion from W. to E. At 6 a band with a few streaks above it, moving slowly to the S., stretched from Orion through Gemini to Leo Minor. 7 a. m. saw a luminous band stretching round close to the horizon, without motion, extending from Pegasus to Serpens. Haze then began to cover the sky, and soon became clouds. A magnetic disturbance, affecting the horizontal force, and to a less degree the declination also, commenced at 2 a. m., and continued several hours after the end of the aurora.

Norember 10, 1882, 3 a. m. to 9.10 a. m.—The sky was cloudy during most of the night. When it cleared, at 3 a. m., no aurora was observed. A faint glow in the N. and NW. may have been auroral. At 5.15 a. m. the clouds again broke away sufficiently to show an arch from Taurus through Pegasus to Lacerta from SE, to SW., partly hidden by clouds and haze (brightness 1). At 8 a. m. the sky partly clouded again, disclosing a motionless band from Orion to Leo, about 5°-8° above the horizon, showing through haze (brightness 0 to 1). At 9.10 a. m. a few faint traces of aurora were visible through the haze and clouds. The magnetic needles were very slightly affected.

November 12, 1882, 3 a. m. to noon.—During the early part of the night a furious storm of wind and snow was raging, accompanied by a violent magnetic storm affecting all three elements, which lasted several hours after the aurora disappeared. Through a break in the clouds at 3 a. m. sinuous bands and streamers (brightness 2) were observed in the N., in and near Ursa Major. At 3.17 the sky was nearly clear, and sinuous bands from the NNW, to ESE, occupied most of the western sky, the ends of the bands being lost in haze, while an incomplete corona formed E, of the zenith (brightness 2). Accurate observation was rendered impossible by the violence of the weather. From this time on the storm moderated. At 4 a, m. a whirling band ran up from Orion's belt in

the SE, towards the Pleiades, and two arched and nearly parallel bands ran along the SW, horizon the upper band the broader and brighter, through Taurus, Cetus, and Pisces into the lower part of Pegasus below the square (brightness 2). It had faded considerably at 4.10, but at 4.17 had developed into two bands of curtains and streamers, with rapid vibration and play of colors, yellow. green, and rose (brightness 3), intermittent, sometimes sinking to 2 or rising in places to 4. At 5 a. m. two yellowish green bands ran from WSW, to WNW, through Aquila to Hercules, with a few streamers on the WNW, end (brightness 1 to 2). At 6 a, m, there were several bands and streamers in the northern sky, the streamers vibrating from W, to E. At 7 a pale arch with stream ers ran from the SE, to SW., about 9° or 10° above the horizon (brightness 1). At 8 there was a sheaf of beams in the NNE, from Leo to Camelopardalis, with slow lateral vibration, changing in brightness from 1 to 2. At 9 a, in, the horizon was encircled by a band of pale quiet white light 10° in breadth, from which arose a perfect fringe of streamers, some approaching the zenith, most of hem, however, not exceeding 10° or 15° in length, and apparently motionless. This display continued for nearly an hour, with but slight change, when a broad white band (brightness 0 to 1) was observed to start from the luminous base in the W. through the Pleiades and Ursa Major. stopping at a point about 30° E, of the zenith. No further change was observed till 11 a. m., when a second like arch was formed about 6 -80 in breadth and 600 in diameter, having its crown in the zenith. From this band streamers shot out and formed a complete corona. At this time the mag netic listurbance was particularly great. The corona continued apparently unchanged and motionless until it faded before the dawn.

November 12 and 13, 1882, 9.30 p. m. to 11.30 p. m .- As soon as the sky grew dark enough to an aurora to be visible, it appeared well developed and probably a continuation of the preceding aurora. At 10.17 p. m. a waying band of light extended across from SE, to NW., bright st in the SE., where it had the curtain form, with the streamers in the same direction. At 11.17 there was a faint streak (brightness 1) through Andromeda, Cassioneia, Draco, and Boötes, with bright cm tains in Pegasus and Cygnus. At 12.17 there was an arch whose extremities bore SE, and NW., and below this, on the horizon, a well marked dark segment, with wavy faint streamers above it. and faint patches of light in Andromeda and Cassiopeia. At 1 a. m. there was a broad bright zone occupying nearly all the western sky, and extending east of the zenith, from Boötes, in the NNW., through Ursa Major, round above Capella to Taurus, in the ESE. The zone was composed of several broad sinuous bands, converging near the horizon, and sometimes developing streamers (brightness 2 to 3). It drifted westward, and had passed the zenith at 1.10, in motion especially on the edge, in the N., and at the zenith, waving and vibrating, with some slight display of colors, yellow, green, and rose. There was a particularly bright portion in the SE. The whole had sunk low in the SW, at 1.17. From 2 to 2.17 a, m, the aurora was reduced to two bands lying low in the SW, from Ophiuchus in the NW, through Aquila to Pegasus in the S., with streamers from the upper band, all growing gradually smaller (brightness 2 to 3). At 3 a.m. a broad bright zone of the usual type crossed the zenith from Orion and Taurus in the SE, to Boötes, with streamers forming a half corona E. of the zenith, centering in Cassiopeia (brightness 2). At 3.10 the half corona was W. of the zenith, with the bands as before, developing wavy curtains at the zenith. At 3.17 there were bands low in the NE., running from Procyon through Leo Minor and Canes Venatici to Boötes, made up of streamers flashing rapidly from N. to S., and showing beneath them a well-marked dark segment (brightness 2 to 3). At 4 a.m. these bands had become curtains; there was a broad band (1) in the S, and sinuous streaks covered most of the sky at right angles, roughly speaking. to the magnetic meridian, converging towards the horizon in the NW, and SE. At 4.10 to 4.17, radiating from Aquila in the NW., near the horizon, and Canis Major, near the SE., bands, streaks, and streamers covered most of the sky, constantly changing and shifting, with much flickering motion. There was a special center of activity in the N., where curtains were developed. At 5 the aurora consisted of two bands, with yellowish streamers. At 6 it was an arch made up of curtains and streamers in rapid motion (brightness 2 to 3). At 7 there were only faint traces around the horizon, while at 8 no aurora was visible, but it broke out again at 9 in the form of a white striated band (brightness 2 to 3), about 30° in width, passing from the SE, to NW., about 3° to 5 SW, of the zenith. There was much wave-like motion from W, to E., with considerable change of form, but not of position. The horizon was fringed with streamers, generally about 260 long and W. horizon. e lower part at 4.17 had olors, vellow. s to 4. motionless. From 10.15 to 10.30 the aurora filled almost the entire southern half of the sky, passing from SE, to NW, north of the zenith. The lower half of the sky was filled with curtains brilliantly colored, green, yellow, and red predominating, in narrow bands parallel to the magnetic meridian, the whole in rapid motion from E, to W, (brightness 2). At 11.20 there was a perfect corona, with curtains in the S, and a luminous band on the northern horizon from the SE, to NW, sending up streamers to the zenith, white and quiet (brightness 1 to 2). At 11.17 the corona still continued, and the whole aurora was of the same general type, but moving slightly. It faded about 11.30 a. m. The magnetic needles were but slightly disturbed up to 3 a. m., when the disturbance became very violent, not subsiding until about 5 p. m. All these elements were affected, especially the horizontal and vertical force, the former decreasing and the latter increasing so much that it was frequently impossible to measure them, while the declination ranged from 310 to 519.

November 13 and 14, 1882, 11.17 p. m. to 1,20 p. m.—The aurora commenced at dusk and was first observed (11.17 p. m.) as a wavy band through Pisces, Perseus, Auriga, Leo Minor, and Coma Berenices, whence a faint streak rose to the Pole star, through Ursa Major. At 11.17 a. m. the same or a similar band passed through Perseus, Draco, Lacerta, Ursa Major, and Canes Venatici, with faint streaks also in Cygnus. At 1 a. m. a rather broad arched band (brightness 0 to 1) extended from Taurus in the ESE, through Auriga to Ursa Major below the Dipper and Canes Venatici, brightest at the northern end, and sending off one or two long streamers at the ESE, end. This had faded greatly and become much broken at 1.10. At 1.17 a broad zone of the ordinary type of sinuous bands crossed the zenith from a point in Bootes, near the northern borizon, to Taurus in ESE. This zone was pale, only reaching a brightness of 1 in a few places. At 2 a.m. this had condensed into a twisted band 4° to 5° wide (brightness 2) from Eridanus on the ESE. horizon through Taurus, where it was much twisted like a smoke wreath, Perseus, close to Cassi opeia, through Ursa Minor and Draco to Corona Borealis. The whole was drifting slowly west ward, having reached Cygnus and Lyra at 2.17, changing but little in character. At 3 a. m. there was a pale band low in the SW., while another zone crossed the zenith, spreading over the eastern sky with the bands much twisted, and forming something like curtains, varying in brightness from 1 to 3, with slight motion, and some faint rosy orange tinges in SE. The extremities were in Monoceros in the ESE,, where it had a curdled appearance, and reached a brightness of 3 at 3.17. At 4 a.m. the aurora was of the same character, but paler (0 to 1), and lying more in the SW. At 4.17 there was a well-pronounced zone, which only reached a brightness of 1 in places, radiating from points in the lower part of Orion in the ESE, and Serpens in the NNW, so broad as to cover most of the sky, arching above the square of Pegasus in the SW. At 5 a. m. two arches ran from Orion through Andromeda to Cygnus, with bright streamers of various colors from yellow to red, blue and green, vibrating rapidly from W. to E. (brightness about 3). At 6 there was an arch from S. to W., with green streamers at the western end. At 7 there were simply traces around the horizon, and at 8 only faint traces. At 9.17 there was a broad, quiet, white nebulous band from Orion through Gemini, Ursa Major, and Canes Venatici to Boötes (brightness 1). At 10.20 there was a corona of pale, white, quiet streamers from the horizon to the zenith (brightness 0 to 1). At 11.10 a. m. pale, white, quiet striated bands running E, and W., filling the sky from about 10° west of Polaris to the southern horizon. Only faint traces were visible at 12.17 p. m., and continued to be visible, especially in Ursa Major and the NW., till broad daylight. The magnetic needles were but slightly disturbed up to 9 a.m., when a disturbance of great violence set in. This had not ended at midnight.

November 14 and 15, 1882, 9 p. m. to 12.15 p. m.—While the twilight was still bright the aurora appeared as pale, vertical streamers in the ESE, in Perseus and Andromeda at about 26° above the horizon, and at 10 p. m. had developed into an arch of streamers still pale (0 to 1), from Leo Minor, some distance above the northern horizon, through Auriga ending in Trangulum, maintaining essentially the same position and character up to 11 p. m., though growing brighter. At 12, midnight, a twisted band 4° or 5° wide passed from Boötes in the N. through Ursa Major and Trsa Minor to Pegasus, and there were also faint bands in Cassiopeia, Andromeda, and Draco. At 1.17 a zone of the usual type crossed 4° or 5° W. of the zenith, from a point low in Tannus in the ESE, through Aries, Triangulum, Andromeda, Cygnus, Lyra, and Corena Borealis to Boötes,

close to the horizon in the NNW. This zone was much twisted in the N. (brightness 2), showing a faint rose tinge in the N. and SE. At 2 a. m. it was in the form of two bands, one from Canes Venatici through Ursa Minor to Andromeda, the other across the zenith from Ursa Major to Taurus (brightness 3). Between this observation and the next the aurora reached its maximum, being a great display of the usual type, bands, curtains and streamers covering the whole sky, with much play of colors, and vibration, fading rapidly. At 3 a. m. there were three bands with streamers, two from Aquila in the NW., through Cygnus and Hercules, and one arch from Pegasus to Aries (brightness 1 to 2), displaying yellow, green and pale blue colors, and vibrating rapidly. Between this observation and the next the aurora was again brilliant, but at 4 a. m. had faded to a quiet band (brightness 0 to 1), round the horizon, and at 5 there were two similar bands from NW. to SE. At 6.17 there was a faint illumination in the southern horizon, and quiet curtains in the N. At 7 a. m. there was a faint band in the SW., from Pegasus through Taurus to Gemini, with pale streamers moving slightly at the western end, and also several patches in Lacerta, Cassiopeia, and Cepheus. At 8.15 there were a few pale, white, quiet streamers between the N. and SE., and no aurora was seen at the next observation; but at 10.15 there was a faint arch from the SE. to SW., with an altitude of about 20°, with the lower edge well defined and showing a dark segment. At 11.15 there were faint streamers in the E., passing from the horizon through Canes Venatici, Coma Berenices, Boötes, and Lyra, and converging to a point just above a and 3 Ursa Majoris. At 12.15 there were very pale streaks in Ursa Major, nearly reaching the zenith, and traces of aurora in the NW, obscured by clouds. The magnetic disturbance of yesterday continued pretty violent up to about 6 a. m., since which time the instruments have been comparatively quiet.

November 16, 1882, 12.15 p. m. to 11.20 a. m.—The aurora did not begin till some time after dark, first appearing as a faint streak of light in Leo Minor. At 1 a. m. there was a pale glow all around the horizon, brightest in the N., when at 3.17 three vertical streaks had developed, the largest running from near Arcturus to Draco, very pale (0 to 1). At 2 a.m. there was a narrow hazy band (brightness 0 to 1) across zenith from a point in the lower part of Taurus in the ESE. through Perseus, Triangulum, and Cassiopeia to Draco, brightest close to the SE, part, where it reached brightness 1 at 2.17, the crown having drifted westward to Cygnus and the band broadened a little, running down closer to the NNW, horizon in Corona Borealis. At 3 a. m. there was a broad, pale zone, much broken (brightness 0 to 1) from the same points in the NNW, to SE., from the SW, horizon to an altitude of about 200, beginning to brighten and develop streamers at 3.10. At 3.17 it was rising in the form of an arch of streamers, approaching the curtain form, till it reached the square of Pegasus, Cygnus, and Lyra, where it began to fade and then develop into a paler zone of sinuous streaks. There was some vibration from E. to W. and a faint green tinge on the upper edge, shading through yellow to pale rose. There was a similar but smaller arch in the E. in Gemini and Cancer, and another in Leo. At 4 a. m. there was a broad zone of the usual type (brightness 2 to 3) from a point in Monoceros close to the ESE, horizon to a point in Serpens in NNW. occupying Orion, Taurus, Auriga, Perseus, Andromeda, Cassiopeia, Pegasus, Cygnus, and Lyra. The eastern edge was the brightest and much twisted. The aurora in the E. was essentially unchanged. There were additional streamers from the tail of Ursa Major to the zenith at 4.10. At 4.17 the bands of the zone were separating and growing paler except the westernmost (brightness 3). At 5 a.m. there was a band with motionless streamers from Canis Minor through Orion to Pisces about 5° to 8° above the horizon, and a paler band shaped like a horseshoe from Orion to Leo. At 6 a. m. a bright band crossed the zenith from Lyra through Ursa Minor to Gemini, moving slowly to the south. At 7 there were two faint arched bands around the horizon. At 8 there was a corona, with its center a little W. of the zenith, covering almost the whole sky. From the center beams extended to bands and streamers. It was nearly gone at 8,20 a, m. (brightness 1 to 2). At 9.17 there was a broad white quiet band (brightness 1) from Andromeda through Cassiopeia, Camelopardalis, and Ursa Minor, ending in Boötes, with also a faint glow on the southern horizon. The band had disappeared at 10.17, and the glow had developed into an arch with its corona at an altitude of about 20°, with short streamers from the arch. There were also streamers 450 long in the NE., E. and S. about 290 above the horizon. At 11.20 there were a few faint quiet streamers in the NE. The needles were but slightly disturbed; most so about 4 a. m.

November 17, 1882, 12.15 a.m. to 12.30 p.m.-At 12.15 a.m. faint streamers were observed in the N., partially obscured by clouds. At 1 a. m. there was merely a pale glow all around the horizon, but ten minutes after there was rather a broad arched streak (brightness 1) running up from close to Arcturus in the N. near the horizon, through Canes Venatici and Ursa Major, ending close above Castor and Pollux. At 1.17 there was a twisted band from the same point in the Nup to Ursa Major. From 2 to 2.17 there was a pale glow all around the horizon, with occasional faint streamers close to the horizon in the SE. At 3 a. m. there was a pale band (brightness 1), divided lengthwise, so the ends overlapped at the zenith, crossed the zenith from Auriga high in the ESE., through Cassiopeia to Draco, reaching down towards Boötes at 3.10 and fading at the E. end. There were also traces in the E. in Orion, Cancer, and Leo Minor, developing into a pale arch of streamers at 3.17, while the rest of the aurora faded. At 4 a.m. there were pale bands and streamers in the NE., developing at 4.17 into a twisted vertical band in the NE. (brightness 1), occupying Leo Minor and the whole of Ursa Major, and spreading pale and hazy toward the zenith. The horizontal force fell suddenly with the development of this band. There was also a pale band in Lyra in the NW. At 5 a.m. there was a pale arch from Hercules to Serpens, and three or four bunches of streamers in Cygnus, Lyra, and Corona Borealis (brightness 0 to 1), and no At 6 a.m. there was a quiet band from Pegasus, through Triangulum to Taurus, with no This was almost hidden by haze at 6.20. After this the sky became covered with clouds, only clearing at intervals. Traces of aurora were observed at 9.17 and 10.17, at the latter observation giving indication of an extensive aurora behind the clouds. Traces were again vistible at 11.20 through the clouds. At 12.15 p. m. the sky cleared, and was observed to be encircled by a broad band of white, quiet light. In a few minutes the sky from the NE, to SE, points became colored a bright rosy red, the color fading away towards the zenith. About the same time a large white curtain formed across the rest of the sky, remaining nearly motionless for several minutes, and then gradually disappeared, while the red color spread farther S., and bright rays shot up towards the zenith, forming a perfect corona, which continued about forty minutes. The streamers of the corona were white and motionless. When the red color first appeared the light was striated with the rays parallel to the magnetic meridian, and several stars were visible showing through the colored portion with undiminished brilliancy. At 1 a. m. traces of aurora were observed in Boötes. The magnetic were almost undisturbed up to 6 a. m., when a violent disturbance commenced, still going on at daylight.

November 18, 1882, 7 a. m. to 12.17 p. m.—The weather was stormy during most of the night, but the clouds thinned away from 7 a. m. to 12.30 p. m., permitting portions of the aurora to be seen. At 7 a. m., a band of streamers vibrating up and down, and also from E. to W. (brightness 1 to 2) was seen stretching from Orion through Aries to Pegasus, while another band without streamers ran from Orion through Perseus and Cassiopeia to Cygnus, moving slowly towards the SW. At 8 there was a faint arch (brightness 0 to 1) from Orion to Pegasus. Traces were seen through the clouds at 9.17 and at 10.17 in the E. and SE. At 12.17 there was a quiet white nebulous band (brightness 0 to 1) from the SE. to the N., reaching an altitude of about 40° above the horizon, in the S.

Norember 18 and 19, 1882, 9.15 p. m. to 9.17 a. m.—During most of the night the sky was covered by thin hazy stratus clouds, through occasional breaks of which traces of aurora were observed from time to time, beginning as early as 9.15 p. m. on the 18th. At 10.15 the sky was clear enough to display a waving band (brightness 1) from Coma Berenices in the NNW, through Canes Venatici, Ursa Major, Ursa Minor, Cassiopeia to Pegasus in the ESE. It was brightest in Ursa Major, where it was broken into streamers. At 11.15 an arch was observed through the haze, very dim and wide in places, broken into three parallel bands, with its extremities bearing NW, and SE. The next hour it was cloudy, but the clouds appeared luminous here and there. At 1 a. m. on the 19th there were traces of aurora through the clouds in the N., and at 3 a. m. traces of bands crossing the zenith from NW, to SE, were seen through the clouds. At 4 similar traces were seen in the NE, and at 8 and 9.17 a. m. in the S. and W., and at the last hour also at the zenith. There was considerable magnetic disturbance during the whole night.

November 19 and 20, 8 p. m. to 11.17 a. m.—Just before the 8 p. m. observation, the sky being clear and the twilight still bright, pale streaks of aurora were observed in the N., high up in the

H. Ex. 44----50

8ky. No aurora was recorded at the 8 p. m. observation. The sky then clouded over and did not clear again until 1 a. m. on the 20th, when there was visible a band from near [s] Ursa Majoris in the NNW, across the zenith to Cassiopeia, with a corresponding band in the ESE, running up towards it but not meeting it, from Tourus through Aries and Andromeda (brightness 1). There were pale broken bands in the W. and an arch low in the NE, in Canis Minor and Leo. The SE. part of the band was gone at 2.17, the eastern aurora was paler, and there was an additional streak in Ursa Major. At 2 a. m. there were two broad streamers in Ophiuchus in the NNW., about 50 above the horizon (brightness 1); pale and shifting at 2.10 to 2.17. At 3 a. m. there was a pale band from the same point in the NNW, to Eridanus in the SE, passing close to  $\beta$  Cygni and through Pegasus. This developed rapidly into a band of curtains and streamers, forming an incomplete corona, which centered near a Cygni at 3.10. These streamers vibrated rapidly from E. to W. and from W. to E. The curtains were 2 to 3 in brightness, the streamers were 1, brightest in the NW.; and brightly colored yellow and green, succeeding one another in the order named, from the horizon up. At 3.17 there was a rosy glow in the NW, and a broad zone across the zenith, made up of writhing, twisting bands of streamers in exceedingly rapid motion, both rotating and shooting from N. to S. and the reverse. There were the usual green, yellow, and red colors, bright, and the brightness was 2 to 3, possibly 4 in places, though much dimmed by the bright moonlight. The magnetic disturbance which had hitherto affected only the horizontal force now extended to the declination, which fell over 6°. At the same time a semi-corona was formed from Ursa Major to Andromeda. At 4 there were streamers all around the horizon except in Andromeda (brightness 1 to 2), white, about 45° long and 10° or 15° above the horizon. The whole faded rapidly. having nearly disappeared at 4.17. The declination increased about 13°. At 5 a.m. there was another complete corona (brightness 1 to 2), centering in Camelopardalis, a few degrees SW. of the zenith. At 6 there were several yellowish-green arched bands with streamers from Gemini through Cepheus, Cassiopeia, Andromeda, and Lacerta to Cygnus, slightly vibrating. At 6.15 the whole had moved a few degrees southward (brightness 1 to 2). At 7 there were two faint arches (brightness 0 to 1), one from Taurus to Pegasus, and the other from Hercules to Boötes. At 8 there was a short, broad, yellowish-green band (brightness 1 to 2), from Monoceros to Taurus in the S., sending up motionless streamers. At 9.17 there was another perfect corona, with the rays brightest and most numerous in the SE., S., and SW., apparently motionless, and white (brightness 1 to 2). The corona still continued at 10.17 a.m., but its rays in the NE. no longer sprang from the horizon, but from a bright arch whose extremities were in the SE, and NW,, and its crown about 40° northeast of the zenith. The rays vibrated slightly; traces of aurora were still to be seen through the clouds at 11.17 a. m., but after that the sky was completely covered. The magnetic disturbance continued during the night, though its maximum was reached between 3 and 9 a.m.

November 21, 1882, 4 a. m. to 12.30 p. m.—The early part of the night was cloudy, and when it cleared at 4 a. m. there was only a pale glow in the N. and NE., and two or three very faint arched streaks close to the southern horizon, which wholly faded away. The sky became clouded at 9, clearing partially at 11.17, when traces of aurora were visible for an instant only through the clouds, apparently without color or motion. At 12.17 a. m. a corona was observed (brightness 3 to 4) in the form of a circle all round the horizon, fringed with short rays, centering towards the zenith, but not reaching it, lasting only a few minutes. Its color was white, and the streamers vibrated slightly. At 12.30 another corona was observed in the form of an ellipse, with its longest diameter E. and N., with long streamers converging to the zenith, and fringed with streamers on the outer edge, col ored bright rose, with interspaces of bright myrfle green (brightness 3 to 4). There was considerable rapid E. and W. vibration, and the display lasted only a few minutes. The magnetic needless were exceedingly quiet up to about 8 a. m., when a disturbance commenced, lasting till 10 p. m., especially affecting the horizontal faces and declination, reaching its maximum at the time of the formation of the corona.

Norember 25, 2 a, m, to 12.17 p, m.—When the sky cleared at 2 a, m, there was observed a forked vertical band in the N, from near the horizon towards the zenith, starting at a point in Buötes, one branch running to the NE, through Ursa Major, the other up through Ursa Minor to the zenith (brightness 0 to 1). This had faded at 2.15, and a hazy arched band (brightness 1) ran from Hercules high in the NW, through  $\beta$  Cygni and the square of Pegasus, disappearing in the

moonlight in the S. At 3 a.m. there were traces of aurora in the NE., which at 3.15 had developed into an arched band (brightness 2) with faint tinges of red and yellow from a point in Monoceros close to the horizon in the ESE, through Leo to a point in Boötes near the N. horizon. At 4.10 there was an arched band (brightness 1), curved into an ellipse in the NE, some 10° or 15° above the horizon, in Canis Minor, Cancer, Leo Minor, and Canes Venatici. This had nearly faded at 4.15, and none was observed at 5 a. m. At 6 an arch crossed the southern horizon from SE. to SW. with streamers on the SE, half, running from Canis Minor, through Orion and Taurus, to Andromeda. The streamers crossed rapidly from W. to E., with play of colors, yellow, green, and red (brightness about 2). At 7 a.m. there was a band (brightness 1 to 2) from Cygnus through Corona Borealis to Boötes, but at 7.15 there was only a faint small arch in Ursa Major. At 8 there were merely faint traces over the NE. horizon, and no more was observed till 12.17 p. m., when there was a corona of long, slender white streamers, a few of them brighter than the rest, stretching about 30° above the horizon (brightness 0 to 1). The whole aurora was much dimmed by the exceedingly brilliant moonlight. The magnetic needles were almost undisturbed up to 7 a.m., when a disturb ance, chiefly affecting the intensity with decrease of horizontal and increase of vertical force, commenced, lasting till 3 p. m.

November 26, 12:30 a. m. to 4 a. m .- Preliminary evapescent streamers were noticed in Ursa Major high in the NNE, at 8.45 p. m. (3.30 local); but no more aurora was seen till at the 1 a. m. observation, when pale streaks were observed in the N., developing at 1.15 into a pale zone of the ordinary type, white and quiet (brightness 0 to 1), across the zenith, converging at points in Boötes in the NNW, and Cetus in the SE, close to the horizon. There were three main bands in the zone, one through Ursa Major and Auriga, one through Ursa Minor, and one through Cassiopeia and Andromeda. At 2 a. m. the western band alone of this zone still remained, and there were besides three or four arched bands of short bright streamers in the NE. in Canis Minor, Cancer, Leo, and Coma Berenices, with considerable vibration from N. to S. (brightness 2 to 3), tinged with green, yellow, and red, while pale streaks and streamers near the zenith moved rather rapidly, tending to form an imperfect corona. At 2.10 the eastern aurora had subsided into pale bands, and one serpentine streak (0 to 1) ran from Ursa Major through Polaris to the square of Pegasus approximately parallel to the magnetic meridian. There was considerable magnetic disturbance with increase of the horizontal force and slight diminution of the other two elements. The aurora had mostly faded at 2.15. At 3 a.m. there was a pale band in the place of the eastern aurora described at 2 o'clock. At 3.15 to 17 there was an arched band with a reversed curve at the SE, end from Canis Minor through Gemini into Ursa Major, gradually breaking into streamers at the northern end. The magnetic needles were comparatively quiet. At 4 a. m. the sky was overspread with polar bands of cloud, which allowed only indistinct traces of aurora to be seen, and during the rest of the night similar clouds prevented the observation of aurora. The aurora was much dimmed by the moonlight.

November 27, 1882, 3 a.m. to 4.10 a.m.—At 3 a.m. part of the pale, narrow, quiet band was observed through the thin clouds in the NE. at right angles to the magnetic meridian. At 4 a.m. there was a broad hazy band (0 to 1) from the NW. to SE., visible only from Cygnus through Cas siopeia, and had moved 20° eastward at 4.10, leaving only traces through the clouds at 4.15. At 5 a.m. a pale yellowish band (0 to 1), motionless, ran from Leo through Ursa Major to Draco. At 6 there was a pale motionless areh from Cygnus through Andromeda to Perseus, and a patch in Auriga (brightness 0 to 1). Clouds prevented further observation. The magnetic needles were comparatively quiet most of the night. There was a slight disturbance at 3.05, the horizontal force rising and then falling below the normal, and another at 10.12, the horizontal force falling slightly.

November 27 and 28, 1882, 9.15 p. m. to 1.15 p. m.—At 9.15 p. m. on the 27th there were faint horizontal streaks through Taurus, Gemini, and Leo in the NE. No more aurora was observed, the sky being partly obscured by streaks of cloud, until 1 a. m., when the sky was clear, and streaks were noticed in the N. and E., which developed at 1.15 into a broad hazy twisted band (brightness 1) from a point in Boötes below Arcturus close to the horizon NNW, through Draco, Ursa Minor, Perseus, and the Pleiades, ending in the lower part of Taurus close to the horizon ESE. From 2 to 2.15 a. m. there was a rather broad zone of the usual type (brightness 2) from a point in Serpens close to the horizon NNW, to a similar point in Orion ESE, occupying Lyra,

nd did not

Cygnus, Andromeda, Cassiopeia, Aries, and Taurus. At 4 a. m. the zone was rather lower, occupying Aquila and the square of Pegasus, and much brighter (3) with motion beginning to develop at the ESE, end. It rose rapidly, being at 3.10 at the position of the 2 o'clock aurora, with very rapid waving and gyratory motion (brightness 2 to 3). At 3.15 it crossed the zenith, reaching each to Ursa Major and Oemini, much paler (1 to 2) and quieter. There was a large magnetic disturb ance, chiefly affecting the horizontal force, which fell very low. At 4 a. m. only traces of aurora were visible. At 5 a. m. there was a band (brightness 2) from Lyra to Ursa Major across the NE., and at 6 a. m. a broad band ran from Pegasus through Cygnus, Cepheus, and Ursa Major to Leo. Another band of the same color and brightness (1 to 2) from Andromeda through Cassiopeia and Auriga to Gemini, both having a rapid lengthwise motion from W. to E., resembling steam or smoke driven by a brisk wind. From 7 a. m. to 1.15 p. m. there were merely traces of aurora visible, though the sky was clear. The traces a 1.15 were low in the SSE, and developed into a pale streak neross the zenith, fading at dawn.

Norember 28 and 29, 1882, 10 p. m. to 10.15 a. m.—The whole night was clear. At 10.15 an arch was observed in the northeast with an altitude of about 25°, its extremities being NNW, to E. by S. The color was a faint yellow (brightness 1). At 11.15 the arch was in a similar position, but somewhat higher. At 12.15 it was still in the same position, but had developed streamers at the NNW, end reaching to Ursa Major. No aurora was visible at 1 a. m., but at 1.10 to 2.15 there was a marrow arched band (brightness 1) from a point in Boötes near the horizon N, through Leo Minor, ending in Gemini below Castor and Pollux, at an altitude of about 25°. From this time to 5 a. m. there was no aurora, but at 5 a band (brightness 0 to 1) crossed the zenith from NNW, to S., from Vulpecula through Cygnus, Cassiopeia, Cepheus, and Camelopardalis, ending in Auriga and Lynx. At 6 the arch was yellow and made of streamers, waving from E. to W., and varying slightly in brightness (1 to 2). Faint traces only were visible at 7 a. m. from Hercules to Boötes. At 8 a. m. there was a motionless band from Pegasus through Taurus and Orion to Canis Minor. Traces only, soon disappearing, were visible at 10.10 a. m., and no more aurora was seen. The magnetic needles were comparatively undisturbed all night.

November 30, 1882, 12.15 a. m. to 11.30 a. m.—The whole night was clear. About midnight, Washington time (between 7.30 and 7.40 p. m. local), there was a low arch in the NE. (brightness 1 to 2) from Taurus, where it was very faint through Gemini, Leo Minor, where it was brightest, and Coma Berenices, sending up faint streamers in the last two constellations. At 1 to 1.15 a.m. there was a broad twisted band, white and quiet (brightness 2 to 3), from a point in Taurus near the horizon in the ESE, across the zenith, through Andromeda, Cassiopeia, Cepheus, and Draco, to a point in Bootes, close to the horizon in the NNW. At 2 a, in the aurora was unchanged in bearing. altitude, and brightness, but started from Orion in the ESE,, and was split in two parts, one on each side of Polaris, while from the southeast end a band was beginning to shoot up towards the northeast. This had developed into an arched band through Gemini and Ursa Major, at an altitude of about 40°, reaching Boötes in the N., while the western bands had almost faded out. At 2.15 these bands had developed into a zone of the ordinary type from the same points of the horizon, reaching W. to Cygnus and Lyra and E. below Gemini. The eastern bands were the brightest (2 to 3), and in the ESE, showed a faint yellow and rose tinge. At 3 a, m, the zone was mostly reduced to a broad band, brightest in the lower edge (2 to 3), along the SW. horizon, with an altitude of about 25° at its highest point, running from Orion's belt below the square of Pegasus to a point in Serpens in the NW. This continued at 3.15, and in addition a zone of paler bands (1 to 2) covered most of the sky as far E. as Ursa Major and Gemini. The southeast base of the zone was very broad, some 20° of the azimuth. 4 a.m. found the aurora in essentially the same position, but much paler (0 to 1), and it was still more faded and broken at 4.15. At 5 a. m. there were two bright (2 to 3) yellowish bands from Pegasus in the NW., one through Cygnus, Cassiopeia, and Gemini to Canis Minor in the S, across the zenith; the other through Taurus to Orion in the SW,, but showing rapid motion from NW. to S. At 6 there was a quiet, greenish band (brightness 1) from Pegasus, through Pisces, to Orion. Traces only were visible at 7 a.m., but at 7.15 a brilliant corona (2 to 3) formed, with its center a little N. of the zenith. The streamers were bright yellow, and moved round the center, vibrating from W. to E. and from E. to W., keeping the same relative position. Other bands and streamers moved in almost every direction. Traces of this corona were still visible lower, occug to develop a, with very eaching east stic disturb es of aurora oss the NE., ajor to Leo. ssiopeia and ug steam or aurora visi-

The magnetic needles were comparatively undisturbed all night.

November 30 and December 1, 1882, 9.15 p. m. to 10.30 a. m.—The aurora began as a few vertical streaks in the ESE, in Aries and Perseus, and developed into a regular arch of streamers (1), crossing through Gemini and Ursa Major into Boötes in the NNW. This had faded at 10.10, and the aurora was the same as at the beginning, with a few additional streaks in Lynx and Auriga. At 11.15 there were traces only of aurora in the S. near the horizon. At 12.10 a bright band crossed the zenith from a Tauri to Hercules, slightly tinged with yellow, and vibrating. At 1.15 a narrow, twisted streak crossed the zenith from ESE, close to the horizon, to the NNW, through Orion, Auriga, Camelopardalis, Ursa Minor, Draco, and Corona Borealis (brightness 1 to 2). From Orion it was broken up into streamers. There was also a pale, hazy, perfectly quiet and regular arch in the SW., reaching an altitude of about 25%. At 2.15 traces only were visible in Orion, and 3.15 traces of bands crossing the zenith from NW, to SE, were seen. At 6.15 two pale white bands (brightness 1) extended from ESE, to WNW., the larger from Gemini, through Auriga and Lacerta, to Cygnus, about 12° or 15° south of the zenith, the second being somewhat shorter and about 10° below the first. At 7.15 several yellowish bands (brightness 2 to 3), vibrating rapidly from W. to E., extended from Andromeda, through Cassiopeia, Camelopardalis, and Ursa Major to Leo and Coma Bereuices. The whole drifted slowly southward. At 8.17 a broad, irregular band of white, quiet light extended from Leo Minor, through Ursa Major and Draco, to Cygnus (brightness 2). At 9.15 two bands (brightness 0 to 1) extended from Aries, through Gemini, to Canis Minor and Cancer, and only faint traces were visible at 10.17. There was a slight magnetic disturbance from 7 to 10 a.m., but otherwise the needles were remarkably quiet.

December 1 and 2, 1882, 9.15 p. m. to 10.17 a. m .- At 9.15 p. m. there was a faint patch of light in Aries in the ESE. After this preliminary flash no more aurora was seen till 12,15 a. m., when there were very faint streamers in Coma Berenices and Canes Venatici, and a broad, low, hazy arch from Coma Berenices, through Boötes, Hercules, Aquila, and Delphinus, to Pegasus, The dark segment was quite strongly marked below the arch. From 1 to 1.15 there were faint horizontal bands low in the NE. from Orion through Canis Minor and Lee, and a very evanescent band from a Boötis to the tail of Ursa Major, and at 1.15 a very faint band across the zenith from Lyra to Taurus (brightness 0 to 1). At 2 to 2.15 the aurora was essentially the same, with the addition of some well-defined streamers (0 to 1) in Leo and Leo Minor. There were also very faint traces crossing the zenith. At 3 a.m. there were very faint traces of a band from Cygnus across Pegasus in the western sky and traces in the east and south. At 3.10 there was a patch of streamers (1) in Coma Berenices and Boötes in the NNE., one reaching up to Ursa Minor. These had faded to traces at 3.15. At 4 a. m. there was a bright (2) yellowish band crossing up through Canes Venatici in the NE., then across through Ursa Major to Lyra near a Lyra, and a corona of streamers (brightness 1) reaching down about 40° from the zenith, incomplete from Ursa Major and brightest in the NNW. Only this portion remained at 4.10, and the band in the north was reduced in size and brightness. The whole was fading to traces at 4.15. At 5 a. m. there were merely faint traces over the horizon from W. to S. At 6 a, m. a yellowish-green quiet band (brightness 1) extended from Andromeda through Aries and Gemini to Canis Minor. At 7 a yellowish band (brightness 1 to 2) with streamers vibrating slowly from E. to W. stretched from Pisces through Taurus and Orion to Canis Major. At 8 an arch (brightness 1 to 2) ran from Cygnus through Cassiopeia and Auriga to Cancer, moving slowly towards the zenith. At 9.17 there was a broad, white, quiet band (brightness 0 to 1) from Coma Berenices through Lynx and Auriga to the Pleiades, and at 10.17 there was a broad, irregular, striated band, white and quiet brightness 1), from Corona Borealis through Ursa Major to Taurus. The magnetic needles were unusually quiet all night, being slightly disturbed about 11 a.m.

December 3, 1882, 4 a. m. to 12.30 p. m.—The first traces of aurora were seen at 4 a. m. shining through the fog, in the form of the upper portion of a pale, regular, quiet arch in the SW., reaching an altitude of about 45°, and an arched streak in the NE. at an altitude of about 60°. The sky gradually became much clearer, and at 5 a. m. a yellowish-green band extended from Andromeda through Aries and the Pleiades to Canis Minor (brightness 1). At 6 a. m. there was a bread, yellowish, quiet band (brightness 1 to 2) across the zenith from Pegasus through Andromeda,

Auriga, Cassiopeia, and Camelopardalis to Leo. At 7 the aurora had the same position and character as at 5. At 8 a.m. an arch (brightness 1) extended from Boötes through Draco and Cygnus to Pegasus. At 9.17 there were two white and quiet bands (brightness 0 to 1) started together from Boötes in the SE, and met in Taurus in the W., one running about 30° above the southern horizon and the other crossing the zenith. At 10.10 the lower band had disappeared, but the one across the zenith remained unchanged, while another band appeared extending from the Pleiades to Persens, Cassiopeia, and Cepheus to near Hercules. At 11.17 there was a white, quiet band (brightness 0 to 1) from the SE, to NW, through the Pleiades and Coma Berenices and close to Ursa Major. Only faint traces were visible at 12.17 p. m., and these had wholly disappeared at 1 p. m. The magnetic needles were unusually quiet, only showing signs of disturbance at 9 a. m and 12 and 1 p. m.

December 3 and 4, 1882, 9.15 p. m. to 1.15 p. m.—At 9.15 p. m. the aurora commenced as pale lines of light in NE, through Gemini and Taurus, with faint streamers in Lynx. At 10.15 there was a quiet arched band (brightness 0 to 1) through Taurus, Gemini, Leo Minor, and Const Berenices, with streamers in Leo Minor and Ursa Major. It was brightest in Leo Minor and Very faint in Gemini. For several hours the bearing of the aurora was unchanged, but it appeared in different constellations as they rose. At 11.15 there were no streamers. At 12.15 the arch passed through Orion, Gemini, Leo, Leo Minor, Coma Berenices, with streamers in Coma and Ursa Major (brightness 1). At 1 a. m. there were merely traces along the eastern sky from the E. to ESE... but these soon developed into an arch of pale streamers (brightness 0 to 1) from Orion's belt in the ESE, through Canis Minor, Cancer, and Leo, ending close to a Boötis, here sending off long streamers towards the zenith. From 2 to 2.15 a.m. there were two principal arched bands, the upper sending off short streamers, starting from a point in Monoceros close to the horizon in the ESE, and meeting at a point in Serpens similarly close to the horizon in the NNW, (brightness 1 to 2), through Gemini, Lynx, Ursa Major, and Canes Venatici, rising slowly and sending off vale narrow bands from the northern end, which gradually stretched up towards the zenith. At 3 a.m. streaks and envel bands, varying in brightness from 1 to 3, covered most of the sky. The start ing points were in Serpens in the NNW, and Monoceros in the ESE. It was brightest in Cygnus and Pegasus, when it formed an irregular ellipse, with its longest diameter N. and S., with consid erable whirling motion, and across through Canis Minor, Leo, Leo Minor, Canes Venatici, Ursa Major, and Hercules, where it was a band of streamers vibrating rapidly from N. to S. The brightest part was slightly tinged with greenish-yellow and rose. At 3.10 it was broken and paler and the eastern band had split into three, and was fading at 3.15, still brightest in the NE. At 4 a. m. there was a faint, low, quiet, and regular arch in the SW. from the NW. to S., reaching an altitude of about 15°, and bright, curling, wreathing bands (2 to 3), which in 10 minutes spread over most of the sky, coming up from a point in Serpens near the horizon in the NW., one main branch crossing the zenith and spreading out to Ursa Major and Gemini; another through Pegasus. There were also bright disconnected whorls in the NE. The main band moved slowly with a waving motion to the west. At 4.15 it was more spread out and not so bright. At 5 there was a bright corona, yellowish in color (brightness 3 to 4), centering a little south of the zenith. The northern streamers of the corona vibrated rapidly in every direction. The corona had disappeared at 5.20, leaving the sky covered with faint luminous bands resembling stratus clouds. There was a magnetic disturbance. At 6 a. m. there were two motionless arches (brightness 1), one through Taurus and Orion to Canis Minor and the other from Sagitta to Boötes. At 7 there were only faint traces of bands. At 8 a band (brightness 0 to 1) extended from Cygnus through Draco, Ursa Minor, Ursa Major, and Cassioneja to Leo Minor and Gemini. At 9 there were merely a few traces over the southern horizon. No aurora was seen at 10, but at 11 a.m. there were two yellowish-green arches (brightness 1), one through Orion and Canis Minor to Leo, and the second from Taurus across the zenith to Coma Berenices. At 12 m. there were only traces of aurora, and at 1.15 p. m. the last of the aurora appeared as a narrow band (brightness 2) extending from Cassiopeia through Perseus to Gemini. The needles were considerably agitated at 3 and 4 a.m., much disturbed at 5 a.m., the horizontal force being too small to register, and again at 12 m. The other two elements were but little affected.

December 4 and 5, 1882, 9.45 p. m. to 1.15 p. m.—A very evanescent streak appeared in Auriga

ion and charo and Cygnus etcd together the southern , but the one the Pleiades o, quiet build and close to suppeared af

the zenith.

At 5 there

ed in Auriga

about 9.45 p. m. After this there was a pale glow around the horizon, beginning to take the form of horizontal bands in the S. and SW. at 1 a. m. At 2 a. m. there was a belt of two or three streaks, white and quiet (brightness 0 to 1), from a point in Monoceros in the ESE, to one in Bastes in the NNW, through Gemini and Ursa Major. At 2.15 the belt was slightly higher, brighter, and more homogeneous. It was brightest in the NNW. At 3 a. m. there was a broad zone of the usual type, but very pale (brightness 0 to 1), with its stationary points in Monoceros in the ESE, just below Procyon and in Serpens in the NNW. The eastern edge passed through Canis Minor, Cancer, Leo Minor, Canes Venatici, and Boötes, the western through Canis Minor, Gemini, Auriga, Camelopardalis, the upper part of Cassiopeia, Cygnus and Lyra, Draco and Hercules. It was somewhat broken and pale at 3.15. At 4 the zone was reduced to two very pale (0 to 1) bands starting together from a point in Hydra c'ose to the ESE, horizon, one crossing about 207 E. of the zenith, and the other through Orion to near the horizon in the SW. At 3 there were merely traces around the horizon. At 6 a pale yellowish-green band (brightness 0 to 1) stretched through Andromeda, Perseus, and Auriga to Canis Minor. At 7 there were two similar arches one above the other from Pegasus through Pisces, Taurus, and Orion to Monoceros. At 8 a, m, a bright band (1 to 2) with streamers waving slowly from W, to E, extended from Pegasus through Cygnus, Lyra, and Hercules to Boötes. At 9 there were merely traces in Cygnus, Lyra, and Hercules. No more aurora was seen till 1 p. m., when there was an arched band (brightness 1) from Andromeda through Lacerta and Cygnus to Lyra. This had faded to traces at 1.15. The magnetic needles were comparatively undisturbed, though up to 5 a, m, the horizontal force was rather greater than usual.

December 5 and 6, 1882, 12.55 p. m. to 8 a. m.—At 11.55 p. m. five pale streamers were seen in Coma Berenices and Canes Venatici in the NNE. These were seen again in the same position at 1 a. m. but very much paler. At 1.15 there were two faint arched bands (brightness 0 to 1) in the E., one from Orion to Gemini, the other from Canis Minor through Cancer. From 2 to 2.15 there were two hazy and quiet bands (brightness 1) stretching from a point in Monoceros low in the ESE, to one in Serpens in the NNW, through Gemini and Ursa Major. The upper band was the broader, and the light was brightest in the ESE. At 3 a. m. there was a broad, pale (0 to 1) zone of the ordinary type with its starting point in the ESE, and NNW, in Monoceros and Hercules, below a Lyrae, about 10° or 15° above the horizon, crossing the zenith and extending west to Cassioneia, Cygnus, and Lyra. It was brightest in ESE., where it also sent off a broad band (brightness 2) through Leo, Leo Minor, and Canes Venatici to Corona Borealis in the N. This band was paler and somewhat broken at 3.15. At 4.15 the aurora was unchanged in character but had spread westward to the Pleiades and the square of Pegasus, with a slow drifting provement to the west. At 5 a. m. there were two arches (bright. i), without motion, one from Cygnus through Cassiopeia and Gemina, and the other from La through Ursa Major to Leo Minor. At 6 there was a pale (0 to 1) yellowish-green arch in the SW, from Andromeda through Aries and Taurus to Canis Minor. At 7 a.m. the aurora was brighter (1 to 2), and formed an arch, with streamers vibrating slowly, extending from Hercules through Corona Borealis and Boötes to Coma Berenices. There was another pale, motionless arch close to the horizon from the SW. to SSE. The weather was hazy at 8 a, m. but traces of aurora were still visible. After this the sky became overcast, preventing further observation. The magnetic needles were unusually quiet, though the horizontal force was rather higher than usual.

December 7, 1882, 3 a. m. to 1.30 p. m.—Though the sky was partially clear at 3 a. m. no aurora was visible except a pale glow along the southern horizon. At 5 a. m. a pale yellowish band crossed from Cygnus through Draco to Canes Venatici, motionless (brightness 0 to 1). Clouds prevented the 6 a. m. observation. At 7 a. m. there was another extensive aurora crossing the zenith. The western and southern limits ran from Pegasus through Auriga and Gemini to Leo, the eastern and northern from Ursa Major through Draco and Cepheus and Lacerta. It was a belt of arches without streamers, varying slightly in brightness (1 to 2). No motion was noticed, but at 7.15 a. m. the position was a little changed. At 8 two yellowish-green bands, motionless, and brightness 1 to 2, extended from Taurus through Orion to Canis Minor and Monoceros. At 9.17 there was a broad, quiet, white arch of diffused light from the SE. to NNW., having at the crown an altitude of 25° or 30°. At the same time a large portion of the sky northeast of the zenith

was filled with bands which united with the first in the SE, and NNW. (brightness 0 to 1). At 10.17 nothing remained but traces of the arch in the southwest. At 11.17 the southern horizon was mottled with faint, white spots, and at the same time a band of white, quiet light (brightness 0 to 1) passed from the NW, horizon through the Pleiades and Gemini a short distance southeast of Ursa Major. At 12.10 p. m. there was an extensive aurora of parallel bands, white and quiescent, running ESE, and NNW., and extending from the southern horizon to a point about 15 north of Cassiopcia. The aurora was unchanged at 1 p. m. but had faded to traces at 1.15. The magnetic needles were somewhat disturbed from 11 a. m. to 1, p. m., the horizontal force being diminished and the declination and vertical force increased.

December 8, 1882, 3 a. m. to 10.15 a. m.—There was a faint glow along the horizon as the twilight faded, and at 3 a. m. there appeared faint traces of streamers in the ESE, below Procyon, At 4 a. m. there was a somewhat sinuous white and quiet band (brightness 1) from a point in Hydra low in the ESE, up through Cancer, Leo Minor, Ursa Major, and Draco, ending near α Lyrae in the NW.—At 4.15 it was brighter (2) in the ESE, more sinuous, and spreading a little, with an additional pale band reaching to β Cygni.—At 5 a. m. a motionless band (brightness 1) extended from Pegasus in the NW, through Aries, Taurus, and Orion to Canis Minor in the SE. This band was in the same position at 6 a. m. but brighter (J to 2).—At 7 a. m. bright bands (1 to 2) extended from Vulpecula to the zenith and N. and E. of the zenith through Cygnus, Lyra, Draco, Hercules, Boötes, and Ursa Major to Leo.—No motion was noticed.—At 8 a. m. a pale band (0 to 1) stretched from Andromeda through Perseus, Auriga, and Gemini to Cancer.—At 9.15 a. m. a broad, bright (1 to 2) band, white and quiet extended from Canes Venatici through Ursa Major and Cassiopeia to Andromeda.—At 10.15 traces only were visible and no more was observed.—The magnetic needles showed no signs of disturbance.

December 8 and 9, 1882, 10,45 p, m, to 2 p, m,—At 10,45 p, m, there was a faint (0 to 1) but definite arch of streamers low in the NE, in Gemini and Caneer. Nothing but a pale glow on the horizon was seen until 12.15 a. m., when there were bright streamers in Canes Venatici and Coma Berenices, and three wavy bands, one through Taurus, the Pleiades, Perseus, Ursa Major, and Boötes, the second through Taurus, Auriga, Ursa Major, and Boötes, and the third through Taurus, Orion, Gemini, Leo Minor, and Coma Berenices. These bands were all pale except in Boötes, where they reached a brightness of 2. At 1 a, m, there was a broad zone crossing a little SE, of the zenith, with its starting points in Serpens in the NW. and Monoceros in the ESE., the eastern edge passing through Cassiopeia and the western through Cygnus and the square of Pegasus, with considerable motion on the eastern edge. At 1.15 the whole of the sky from Pegasus in the SW, to Gemini in the NE, was covered with serpentine bands and streamers, one starting from Cygnus in the NW, and running towards the SE, through Cassiopeia to the Hyades, where it turned on itself and ran along the NE, sky through Auriga and Ursa Major, here blending into a bright mass of curtains and whorls in the N. There was considerable motion, both twisting and vibratory, the whole moving westward rapidly. There were faint colors and a brightness of 2 to 3. The declination fell about a degree and a half. At 2 a.m. the western portion was nearly gone, and the eastern formed three or four bands from Serpens through Ursa Major and Canes Venatici to Gemini and Cancer, where they curled round into curtains (brightness 2). There was a magnetic disturbance specially marked by a high horizontal force. At 3 a, m, nothing was left except faint traces of a band from the same starting points across the zenith through Cassiopeia. The magnetic needles were nearly back to their normal position. At 4 a.m. these traces appeared as at the last observation, and had nearly disappeared at 4.15, while a patch of aurora was beginning to develop in the lower part of Leo, low in the NE. At 5 a.m. there were merely traces in the N. At 6 several vellowish-green bands extended from Pegasus through Triangulum, Aries, Taurus, Orion, Auriga, Gemini, and Canis Minor to Cancer, with some quiet streamers in Cancer (brightness 1). At 7 a, m, a zone of yellowish-white bands crossed the zenith through Cygnus, Cassioneia, Perseus, Camelopardalis, and Lynx to Leo, with a rapid waving motion (brightness 1 to 2). At 8 a. m. there was a faint (0 to 1) motionless band through Hercules, Lyra, and Draco to Boötes and Coma Berenices. At 10.10 and 12.10 p. m. there were faint traces only visible. At 1.10 p. m. a band (brightness 1) extended from Leo Minor through Ursa Major and Ursa Minor to Cepheus' and faint streaks ran from Gemini towards Ursa Major. Patches of aurora were also visible s 0 to 1). At thern horizon ht (brightness nce southeast ite and quies. int about 15" at 1.15. The d force being

December 9 and 10, 9 p. m. to 11.10 a. m .- At 9 p. m. the aurora began as a taint band in the E. in Taurus, Gemini and Lyra. At 10.15 there was an arch from Taurus through Orion, Gemini, Cancer, Lyux and Leo Minor to Coma Berenices. It was very faint, except in Taurus, Coma Berenices and Leo Minor, and in the latter constellation was broken into streamers, brightness 1. At 11.15 there was merely a faint arched streak through Cancer, Gemini and Lynx. At 12.15 a.m. the faint arch was in nearly the same position, but extended through Orion, Cancer, Leo Minor and Coma Berenices. There were also two stationary streamers (brightness 1) in Coma Berenices and Canes Venatici. At 1 a. m. the pale arch (brightness 1) extended from Orion's belt in the S.E. up through the lower part of Gemini, Leo Minor, Lynx, Canes Venatici and Boötes, ending below Boötes in the N. It was much paler at 1.15. At 2 a. m., there was in the E. a belt of two or three pale bands, the third and lowest very indistinct, starting from a point in Monoceros in the ESE, near, but not on, the horizon, through Gemini, Lynx and Ursa Major to Boötes in the N. (brightness 1). At 2.15 it was condensed to a single band (brightness 2), the lower end passing through Canis Minor, Leo Minor and Canes Venatici to Boötes. It was brighter in the ESE. From 3 to 3.15 there was an arched, slightly sinuous, band from a point in Hydra low in the ESE, through Leo, Coma Berenices and Boötes to a point in Hercules in the NNW, where it sent up a pale streamer into Draco. It was somewhat convoluted in the ESE, (brightness 1). At 4 to 4.15 an arched band (1) starting low in Leo in the E. ran through Coma Berenices and faded out high in Boötes in the NNE. It was fading slowly, and there were also traces in the S. At 5 two short bands brightness 0 to 1) extended from Pisces through Triangulum to Perseus, and the other from Pegasus through Cygnus and Lyra. At 6 there were merely traces on the southern sky, but at 7 a band of streamers (brightness 2 to 3) in rapid motion from W. to E., and changing color from vellow to green and red, extended across the western sky through Pisces, Andromeda, Perseus, Auriga, Taurus and Orion to Canis Minor. At 8 there was a quiet yellowish arch from Pegasus through Cygnus and Draco to Boötes high in the NE.; 9.10 a. m. showed a broad, low, quiet, white arch on the southern horizon from the SSE, to WNW, with a segment of an arch in the north and a quiet corona of faint white streaks at zenith. The arch in the S, was still visible at 10.10, but the aurora had faded to mere traces at 11.10. The magnetic needles were comparatively quiet all night, though both horizontal and vertical intensity read somewhat higher than usual.

December 11, 1882, 2 a. m. to 2.10 p. m.—At 2 a. m. a broad band (brightness 2) showed across the zenith from NW, to SE,, while the clouds were still so thick as to allow but one or two stars to be seen. This was wholly gone at 2.15, but there were traces of a similar band at 3, which was much brighter and better defined at 3.15. At 4.15 broad, bright, shifting, and sinuous streaks in capid motion across the zenith. This must have been a very brilliant aurora, as it showed brightly through the clouds and was accompanied by a large magnetic disturbance, with decreased intensity and increased declination. After 8 a. m. the sky cleared, but only traces were observed (at 10.10 a. m.) until 1 p. m., when there was a pale (0 to 1) zone of five distinct bands running NW, and SE.; two of them from Gemini to Boötes, one through Leo Minor, and the other through Ursa Major, two from Auriga to Corona Borealis, one through Ursa Minor, and the other through Cassiopeia and Cepheus, and the fifth from Perseus to Hercules through Andromeda and Lacerta. The middle band was the brightest. At 2 a. m. there were faint traces at the zenith, which were wholly gone at 2.12. Besides the disturbance already mentioned there was a lesser one just before

and during the zone aurora last noted.

December 11 and 12, 1882, 9.15 p. m. to 1 p. m.—At 9.15 p. m. an arch surmounted by streamers extended from Cetus through Taurus, Auriga, Gemini, Cancer, Lynx, and Leo Minor. It was very faint, except in Taurus, where the streamers reached a brightness of 2, with the light constantly varying in brilliancy. At 10.15 a similar arch extended through Taurus, Orion, Gemini, Cancer, Leo Minor, Leo, and Coma Berenices to Boötes, with a brightness of 1, except at the ends, where it was 2. There were also faint bands extending, one through Boötes, Draco, Cepheus, Cassiopeia, Andromeda, and Pisces, and the other through Corona Borealis, Lyra, Cygnus, Pegasus, and Pisces with a large mass of luminous haze in the SW., extending from Boötes to Aquila. There was little

H. Ex. 44----51

or no motion. At 11.15 there was an arch through Orion, Gemini, Leo Minor, and Coma Berenice. (brightness 1), with streamers in Coma Berenices and Caues Venatici. At 12.15 there was a simi lar arch through Orion, Gemini, Lyny, Ursa Major, Canes Venatici, and Boötes, and a streak in the N, shooting up from Boötes through Corona Borealis and Draco to Cepheus. At 1 a. m. a sinnon band (brightness 2), starting from the lower part of Orion in the ESE., extended through Gemini, Ursa Major, Canes Venatici to a point low in Boötes in the NNW, with a band below it not quite so bright going only half way to the west, and a still more indistinct third band. The middle band was the brightest at 1.15, and what had been mere traces of bands starting from the same point and crossing west of the zenith had developed a brightness 1. At 2.15 the band (brightness 1 to 2) now started in Monoceros in the ESE, and passed through Canis Minor, Cancer, Leo Minor and Canes Venatici to Boötes, with the western band very faint, and brightest in the NNW. At 3 a. m. most of the sky was covered with luminous haze somewhat segregated into bands from the NNW, to ESE, one brighter than the rest (nearly 1) from Hercules across the zenich, one from Hercules to Orion through Lyra, Draco, Cepheus, Camelopardalis and Auriga. The eastern band of the last observation had paled to 1, and the whole was fading at 3.15. At 4 there were several faint bands, the most distinct (brightness 1) in NNW. from Hercules in the NNW, up through Lyra, Draco, Ursa Major, and Leo Minor to Leo in the ESE. This had moved west about 15° and had faded to a trace at 4.15, and the only distinct band (0 to 1) was in the south from Monocerc to Orion's belt. At 5 a. m. several bright (2 to 3) yellowish green bands moving slowly, one band composed of streamers vibrating rapidly from W. to E. extended from Pisces through Cetus. Aries, Taurus, Orion, Gemini, and Canis Minor to Cancer. At 6 a.m. there were several patches of faint streamers (0 to 1) in the E. and N. At 7 a.m. quiet bands (brightness 1) ran from Cygniss through Andromeda, Cassiopeia, Auriga, and Gemini to Leo and Cancer. At 8 a.m. a quiet band (brightness 1) extended through Cygnus, Draco, and Böotes to Leo. At 9.10 a, m. a faint white quiet band lay along the horizon from the NE, to the W., and from NE, to NW, a (0 to 1) quiet band at an altitude of about 25°. The band on the horizon continued at 10, but had faded somewhat, and there were traces of (0 to 1) aurora in the NNWW, and NNE. The aurora was the same at 11.10 with the addition of faint patches in the NE, and ENE. At 12.17 the entire southern half of the sky was covered by broad parallel bands running from the NE, to SW., with a broad band on the northern side at an altitude of about 48°. The magnets were considerably diturbed. At 1 p. m. pale bands running from ESE, to WNW, covered the sky from Leo Minor to Andromeda, but at 1.12 there were only traces in the SE, and faint traces of several bands through the zenith and Ursa Major. Apart from the disturbance above mentioned the needles were very quiet, though early in the evening the horizontal force was rather high.

December 12 and 13, 1882, 11.15 a, m, to 1 p, m.—At 11.15 p, m, there was a faint flush in the NE, in Cancer and Gemini, but the sky soon became overcast and did not clear again till 6 a, m, when there was a broad, faint (0 to 1), motionless band from Persens through Auriga, Camelopan dalis and Ursa Major to Leo Minor and Coma Berenices. At 7 a faint (0 to 1) band ran from Auriga through Cassiopeia, Cepheus, Cygnus, and Corona Borealis to Boötes. Clouds interfered greatly with the observation of the rest of the aurora, though traces were observed through the haze and clouds at 8, 9, 10, and 10.10 a, m.—At 1 p, m. patches of pale white light were seen through breaks in the clouds near the southern horizon and at the zenith. The magnets were comparatively quiet, though the horizontal force was high early in the evening and lower toward midnight.

December 14, 1882, 2 a, m, to 12.10 p, m,—Beginning with the darkness there was more or less pale glow along the NE, horizon, but no definite aurora till 2 a, m., when there was an arched band (1) from α Canis Minoris through Caneer to Leo Minor, where it disappeared in the clouds. This was much fainter at 2.15. At 3 there was a broad hazy (0 to 1) band starting in Monoceros in the ESE, up through Canis Minor, Caneer, Lynx, and Ursa Major, where it faded out. At 3.15 it extended on to Hercules in the NNW. At 4 it had merely risen slightly, but at 4.15 it had developed into a broad, hazy, and somewhat sinnous band (1 to 2) from Hydra in the ESE, to Hydra in the NNW, through Caneer, Gemini, Lynx, Auriga, Camelopardalis, Ursa Minor, Cepheus, Draco, Cygnus, and Lyra, slowly drifting westward. At 5 a, m, a motionless band (brightness 1) extended from Pisces through Taurus to Orion. At 6 there were two motionless yellowish green

na Berenice. e was a simi streak in the m. a simum nigh Gemini. wit not quite The middle com the same d (brightness er, Leo Minor e NNW. At 3.15 it if had devel-SE, to Hydra or, Cepheus, brightness 1) llowish green bands (brightness 1 to 2), one from Pegasus through Aries and Taurus to Gemini, and the other through Pegasus, Cygnus, Draco, and Canes Venatici to Coma Berenices. At 7 a. m. a yellowish-white arch (brightness 2) rapidly waving, extended from Andromeda through Cassiopeia, Camelo-pardalls, and Ursa Major to Leo Minor and Coma Berenices. At 8 there was a faint (0 to 1) band low in the SE., through Cetus, Taurus, Orion, and Monoceros. At 9.17 there was a broad white quiet band in the SW. horizon from SE. to NNW., and faint parallel bands running SE. and NW. covering the sky from the SW. horizon to the zenith. The aurora was essentially unchanged at 10.17. At 11.10 the band on the border of the horizon had disappeared and the other bands now of similar bands across the zenith were visible at 12.10 p. m. There was a slight disturbance at 9 a. m., chiefly affecting the horizontal force.

December 15, 1882, 1.12 a. m. to 12.15 p. m.—More or less pale glow and very faintly luminous haze was noticed earlier, but no definite aurora till 1.15, when there were traces of faint streamers in the NE., in Cancer and Canis Minor. At 3.15 there was a faint luminous band extending from tanis Minor, through Gemini to Lynx, and a faint band of motionless streamers through Lyra, Hercules, Draco, and Ursa Major to Canes Venatici (brightness 0 to 1). At 4.15 there was a quietyllowish arch from Leo through Lynx, Camelopardalis to Persens and to Triangulum. At 5.15 traces only were visible. At 6.17 traces of a band running 8E, and NW, were visible through the clouds. At 10.15 there was a white, quiet arch (brightness 0 to 1) spanning the SW, horizon from 8E, to NW., with an altitude of about 10°, and also a few bright (0 to 2) streamers in the NE. At 12.12 p. m. there were traces of a band running from Tanrus to Boûtes, between Gemini and Auriga, and traces of patches near the northern horizon. The needles were quiet till 12 m., when the horizontal force began to fall, going very low between 3 and 4 p. m., and then gradually rising, the other two elements meanwhile reading slightly higher.

December 15 and 16, 1882, 8.10 p. m. to 2.45 p. m.—At about 3 p. m. of the local day, while the sky was still quite light, there appeared stretching across the zenith from SE, to NW, a broad hazy hand running through Pegasus, Andromeda, Cassioneia, Cepheus, Ursa Minor, and Ursa Major. Its color was a deep, clear crimson, paling somewhat toward the extremities. It was brightest in Cassiopeia and then faded and became brightest in Ursa Major (brightness 1 to 2), but was wholly gone in about 15 minutes. At 9.15 ruddy streamers, particularly rosy in the N. and S., filled the whole eastern half of the sky centering in Cepheus. These also soon disappeared. At 10.15 they had reappeared as before with some additional streamers on the west, forming a cape round the zenith. These showed rapid motion shooting from the zenith, and faded soon. At 11.15 there was simply a belt of streamers showing only a faint rosy tint across the eastern sky from Boötes to the Pleiades and Perseus. At 12.15 a band (brightness 1) bearing short streamers at intervals pacced through Orion, Gemini, Lynx, Ursa Major, and Canes Venatici across the NE, sky. There were streamers in Boötes and one long one from Corona Borealis, through Cepheus and Draco. Nearly the whole sky was covered at 1 a. m. In the NE, were three bands of streamers from NNW, to ESE,, the highest passing a little east of the zenith, breaking in on the corona which centered near Polaris, its streamers reaching down to Cygnus and Lyra, and forming curtains in the W. which reached down nearly to Pegasus. The brightest was 1 to 2, constantly changing while the band and streamers shifted, continually twisting and waving slowly. At 1.15 the corona was mostly east of the zenith and the western aurora had assumed the form of a broad zone from Orion to Hercules, the highest part taking in Cassiopcia, Andromeda, and part of Pegasus. When the light reached a brightness of 2 it was tinged with green and rose. At 2 a. m. it was all west of the zenith in a broad zone of three main bands from Orion in the SE, to Serpens in the NW., the highest through Andromeda and the lowest below the square of Pegasus. These bands were made up of streamers flickering rapidly from the W. to E. At 2.15 there were four bands in the east, the highest extending along from Canis Minor to Orion and converging in the N. The lowest passed through Gemini and Ursa Major while the rest filled the eastern sky nearly to the zenith, when they were succeeded by a broad zone with the same origin as at 2 a. m., passing through Cassiopeia. The color was greenish, with tinges of rose (brightness 2 to 3), and they shifted and waved slowly. At 3 a. m. the main body of the aurora was in essentially the same position but had paled to 1, was somewhat more diffused, with a convoluted

mass of curtains in the NW, in Delphinus and Vulpecula. At 3.15 it was more broken and still paler with some bright patches in the NE. At 4 a.m. the eastern end of the zone stretched from Leo in the E. to Canis Minor in the ESE., but the whole converged to Serpens in the NNW. The upper band passed through Leo and Gemini and below Cassiopeia, while the remaining four or five bands filled the whole southern and western sky nearly to the horizon. They were all single ous (brightness 2 to 3) and the upper band was beginning to develop coronal bands, which vibrated rapidly, north of the magnetic meridian S. to N., south of it N. to S. The bands were more broken and paler at 4.15 and a large corona was rapidly developing. At 6 a, m, five bands covered nearly the whole sky, some made up of streamers in rapid motion, others motionless (brightness | to 2) At 7 there were three bands, yellowish, and brightness 2 to 3, one from Cancer through Ursa Major and Draco to Cygnus, one from Gemini to Cygnus across the zenith, and the third from Cauis Minor to Andromeda through Perseus. At 8 a. m. there was a faint arch from the S. to SW, from Leo to Orion and a few patches in the E. (brightness 0 to 1). At 9.15 there was a white and oniet semi-corona in the S. from E. to W., and from 10° above the horizon to the zenith (brightness 1 to 2). At 10.15 there was very little change in the character of the aurora except that it had anproached nearer the zenith on the southern side, and a broad band with streamers extended along the southern horizon from E. to W. There were also a few streamers on the northern side forming a nearly complete corona. At 11.15 the band along the horizon had disappeared and the main body of the aurora shifted north of the zenith, and grown paler (1). There was slight motion. At 12.15 p. m, there was a white, quiet arch on the southern horizon from the SSE, to the W, with but 10° altitude, a band from the SE, through Boötes, Canes Venatici, near Ursa Major, through Auriga to Taurus, and streamers in the SE, and W. The whole was white and quiescent (brightness 0 to 1); At 1 p. m. the band on the southern horizon was unchanged and there was a complete corona. At 2 n. m. there were faint traces in Cassiopeia and Auriga, but at about 2.30, although the sky was quite bright, streaks fully I in brightness flashed up in the NW, and crossed the zenith to the SE, while streaks and streamers forming almost a corona in very rapid motion, both circling and vibrating appeared and disappeared round the zenith with great rapidity. A magnetic disturbance of considerable violence commenced about 10 p. m. December 15, and lasted till 5 p. m. De-

December 17, 1882, 3.15 a, m, to 11.15 a, m,—A faint streak or two was noticeable in the S, and SE, at 12.15 and 2 a, m., but there was no definite aurora till 3.15, when there was a pale band of streamers (brightness 0 to 1) in the E, from Regulus to Procyon and a still paler band from Procyon in the ESE, to Hercules in the NNW, passing through Ursa Minor close to the zenith. At 4 a, m, there was a partial corona (brightness 1) centering near the zenith extending in azimuth from Auriga in ESE, to Cygnus in NNW, with its streamers longest, about 50 degrees long, in the constellation Ursa Major. There was also a fan-shaped bunch of secondary streamers in Leo in the E.—It had faded at 4.15, except the lower streamers in the E, and NE.—At 5 there were merely access in the SW, and S, and no more was seen till S a, m, when there were two faint bands from Andromeda to Orion, and the other from Taurus through Orion to Hydra (brightness 0 to 1). From 9.15 to 11.15 there were merely faint traces of aurora through the clouds which obscured the horizon. The magnetic needles were comparatively quiet all night.

December 17 and 18, 1882, 11.15 p. m. to 7 a. m.—At 11.15 p. m. there was a faint arch without streamers, motionless, in the NE., passing through Gemini, Lynx, Leo Minor, Canes Venatici, and Coma Berenices. Between 11 and 12 pale shifting streamers developed above this arch, but were gone at 12.15, when there was a waving band of pale, hazy light passed through Orion, Gemini, Auriga, Lynx, Ursa Major, and Canes Venatici, and also streamers in Ursa Major, Camelopardalis, Ursa Minor, Draco, and Cepheus (brightness 0 to 1). No more aurora was seen except faint traces at 2 and 7 a. m.—The magnetic needles were undisturbed all night.

December 18 and 19, 1882, 10.15 p. m. to 2.12 p. m.—At 10.15 there was a band of waving white light from SE, to NW, nearly overhead through the constellations Corona Borealis, Hereales, Draco, Cygnus, Andromeda, Cepheus, Triangulum, and Pisces (brightness 1 to 2). At 11 p. m. there was only a faint patch of light in the south in Pegasus, Vulpecula, and Delphinus. At 12 there was simply a narrow arch in the south with its extremities bearing SE, and SW, and its crown at an altitude of about 25 degrees (brightness 0 to 1), but at 12.30 it had developed into a

oken and still tretched from NNW. The lining four or were all sinnihich vibrated more broken overed nearly itness I to 2% h Ursa Major 1 from Canis to SW. from rite and oniet rightness 1 to at it had anstended along side forming he main body i. arch without Venatici, and rch, but were rion, Gemini, melopardalis, t faint traces

vaving white is, Hereales, At 11 p. m. inus. At 12 SW, and its doped into a

brilliant display, beginning as four or five bands of streamers across the western sky, from Orion in the ESE, to Hercules in the NNW., the highest through Cassiopeia and the lowest close to the horizon (brightness 3 to 4). The streamers were in rapid motion, vibrating in alternate bands from N. to S. and vice versa, with the rapidity of lightning, while the changes in color and brightness were almost instantaneous. The colors were green, yellow, and rose (one of the party says he saw blue), the latter especially bright and approaching a peach-bloom color. The motion was mostly confined to the middle of the bands and most violent near the zenith, where smaller bands and coronal streamers were shooting and twisting. It soon spread east of the zenith, developing from the NW, in one specially brilliant band of streamers in rapid vibration through Ursa Major and Gemini. Other bands developed across the NE, sky, while the western aurora faded, and globes of red light shot up from the NW, at 12.50-55. At 1 the bands in the east were twisted and carled into spirals and fading at 2 in brightness and the two bands through Ursa Major and Cassiopeia still remained motionless, and brightness 1 to 2. At 1 all had faded to brightness 1 and become hazy and the colors were very faint. Polar bands of cirro-stratus clouds were distinctly seen across part of the aurora when the display was at its height. There was a magnetic disturbance with high easterly declination and rather low horizontal force. At 2 a. m. there was nothing left but three or four bands starting in the clouds in the ESE,, two of them reaching Hercules in the NW., one through Canis Minor, Gemini, Lynx, and the upper part of Ursa Major, and the other through Orion, Taurus, Perseus, Andromeda, Lacerta, Cygnus, and Lyra, and a slightly brighter band in the W. from Aquila to Pegasus (brightness 1). All were slightly brighter (1 to 2) and somewhat broken at the NW, end. The needles were very near their normal position, At 3 a.m. the sky was nearly covered with polar bands and between them were traces of the auroral bands as before, brightest (nearly 2) in the NW, and NE. The declination was reading very low. At 4 a. m. the bands overhead were very pale, with a bright patch in the ME, and a similar one in the NNW. At 4.15 the needles were nearly back to their normal position and remained undisturbed the rest of the night. There were traces seen at 5 a.m. and again at 10.10 a. m., but at 2.12 p. m. four narrow streamers (brightness 0 to 1) ran up from the NNW, horizon and met in Auriga vibrating very rapidly between Gemini and Taurus. This was the last seen.

December 19 and 20, 1882, 11.15 p. m. to 3 p. m.—At 11.15 p. m. there was a faint arch (brightness 0 to 1) in the NE, through Orion, Gemini, Leo Minor, Canes Venatici, and Coma Berenices; this latter growing gradually paler till nearly 12 midnight, but had faded at that observation. At 1.15 there was a yellowish, quiet, and regular arch (brightness 1), quite narrow, from Canis Minor in the ESE, through Cancer, Leo Minor, Lynx, and Canes Venatici, ending in Boötes in the NNW. At 2 a. m. there were rounded, hazy patches in Canes Venatici, and a "zone" of three or four bands from a point in the upper part of Serpens, in the NW., through Cygnus, Lyra, Cepheus, and Cassiopeia, and then dwindling to a single band through Perseus and Taurus, fading in Orion. The whole had faded to traces at 2.15. At 3 a. m. there was a bright sinuous yellow band in the NW. (brightness 2 to 3) from Serpens close to \( \beta \) Cygni and through Pegasus, fading under the moon. At 3.15 these had risen and developed into a very extensive zone (brightness 2), with its starting points in Orion in the SE, and Serpeus in the NW., stretching in breadth from Pegasus to Leo. The streaks were yellow and very sinuous, some spiral in Cygnus, with a rather slow writhing motion at the zenith. There was a sudden and violent magnetic disturbance, the horizontal force falling too low to read and the eastern declination increasing over 1°. From 4 to 4.15 there was a sinuous, broken arched band, rather narrow and yellowish (brightness 1 to 2), from Leo in the E., through Coma Berenices and Boötes, to Hercules in the NNW., and at 4.15 also a pale streamer up into Lyra. The magnets had become quiet. At 5 a.m. there was a faint, motionless band (brightness 0 to 1) above the southern horizon, and at 6 merely traces in the SW. At 8 a.m. there were traces of a very faint corona, resembling luminous clouds, and the needles were very much disturbed, the E. declination increasing 5°. At 9.10 there were only faint traces of aurora, but the disturbance continued. There were also traces at 10.10 a. m., after which no more was seen till 1 p. m., when there were two quiet bands (brightness 0 to 1), one from Cassiopeia through Cygnus and Lyra to Hercules, and the other from Gemini through Leo Minor and Canes Venatici to Corona Borealis, and a corona in Ursa Minor (brightness 0 to 1), moving sluggishly. At 2.15 p. m. there still remained traces of the corona in rapid motion, and also traces of the northern band, and at 3 p. m. there

were still traces in the NW. This last appora was accompanied with a violent magnetic disturbance.

December 21, 1882, La. m. to 3 p. m.—At 1 a. m. there was a curved yellow band in the NW. (brightness?) from just below a Aquila towards Pegasus, but more or less obscured by the bank of clouds that lay on the western horizon, and still more obscured at 1.15. At 2.15 a. m. an arched band, somewhat sinuous (brightness 2), from Hercules in the NNW, through Corona Borcalis, Canes Venatici, Leo, and Leo Minor, ending in the haze. It was gradually breaking into streamers. It had risen at 2.15 about 52 higher, with considerable flickering vibration in the streamers, showing pale colors, green, yellow, and red, not rose (brightness 2 to 3); and there was also a zone (brightness 1 to 2), with its starting points in the SE, and NW, hidden by hazy clouds, and crossing the zenith W, of Polaris and drifting slowly westward. At 3 a.m. there was a rather pale band coming from the clouds near Cancer in the ESE, across the zenith from Ursa Major to Cassioneia and ending in the clouds in the NNW. At 3.15 it was partly faded, and finally obscured by clouds. At 4 a, m, there were only traces in the N. through the clouds which now covered the sky. At 5 a. m. bands with streamers vibrating from W. to E. and back, yellowish in color, and brightness 1 to 2, ran from Orion through Taurus and Aries to Pegasus. At 6 a. m. a quiet band (brightness 1) extended from Pegasus through Cygnus, Draco, and Ursa Major to Leo, while at 8 traces only were visible through the haze. At 9.10, 10.10, and 12.10 faint traces were seen. At 1 p. m. the aurora was extensive in bands and streamers (brightness 0 to 1), paling and vanishing quickly. The bands extended from Gemini and Auriga to Ursa Major, and from Hercules through Corona Borealis and Canes Venatici to Leo Minor; the streamers through Cygnus and Lyra and from Ursa Major to Ursa Minor, forming half a corona. There were also streamers up from Boötes. At 2.12 p. m. there was a sinuous band (brightness 0 to 1) in rapid motion, starting near Taurus and running through Persons and Cassiopeia to Cepheus. At 3 p. m. there were faint traces of a band and a few streamers in the N. and NNW. The needles were more or less disturbed during the whole twenty four hours, the disturbance being at its highest at 2 and 3 a.m.

December 21 and 22, 1882, 11 p. m. to 11 a. m .- At 11 p. m. there was a faint streak through Beötes, Coma Berenices, Leo Minor, and Gemini. At 12.15 a. m. there was a faint regular arch through Orion, Gemini, Leo Minor, Coma Berenices, and Boötes. At 1 to 1.15 a, m, the arch was still narrow and greenish (brightness I), from the ESE, to NNW, through Canis Minor, Cancer, Leo Minor, Canes Venatici, and Boötes to Serpens. At 2 a. m. there was a very pale and somewhat sinuous band (brightness 0 to 1) from Monoceros in the SE, through Orion, Taurus, Perseus, Cassiopeia, Cepheus, and Cygnus to Hercules in the NW. This had drifted W. to Andromeda at 2.15, and a short band had developed in the SE, from Canis Minor to Leo (brightness 1 to 2). This band was rather broad, and flared into short hazy streamers on the upper edge. At 3 a. m. there was a broad zone of the usual type across the zenith from Monoceros in the ESE, to the NW., where its base occupied 200 in azimuth in Hercules. The eastern boundary passed through Leo and Ursa Major, while the main zone spread west to Cassioneia, and the northwestern bands reached Andromeda and Pegasus. At 3.15 it was brighter (brightness 1 to 2) and had spread about 100 each way, showing faint tinges of color in the E. and broken into cloudlike masses in the SW. At 4 a. m. only the extreme western part of the eastern band remained, and the whole had faded to traces at 4.15. At 5 pale traces of bands crossed the zenith from N. to S. At 6 a, m. a yellowish, quiet band (brightness 0 to 1) ran from Pegasus through Perseus, Auriga, and Gemini to Cancer. At 7 a. m. there were quiet bands (brightness 0 to 1) from Crion through Taurus, Auriga, Lynx, and Ursa Major to Leo and Coma Berenices. Faint traces were seen over the southern horizon at 8 a. m., and the last faint traces were noticed at 11 a. m. The needles were quiet up to 3 a. m., when they were considerably disturbed, the horizontal force being most effected. This dis turbance lasted three hours, and there was another slight disturbance at 5 and 6 a.m.

December 22.and 23, 1882, 11.55 p. m. to 2 p. m.—At 11.55 p. m. there was a pale, regular arch in the NE. from NNW. to ESE., the altitude of the crown being about 25°. This had wholly disappeared at 12 midnight. Nothing more was observed till 2 a.m., when there was a broad, hazy band across the zenith from Monoceros, in the ESE., to Hercules in the NW., through Gemini, Auriga, Camelopardalis, Ursa Minor, Cepheus, Cygnus, and Lyra. This had drifted west and faded to a trace at 2.15, and in the NE, there had developed three or four sinuous and somewhat convo

ie disturb.

a the NW. the bank of an arched anis, Canes camers. It rs, showing (brightness g the zenith ng from the ading in the

tlar arch in folly disapfroad, hazy gh Gemini, f and faded that convoInted bands (brightness 1 to 2), and yellow, from Hercules to Leo in the E., the brightest through Ursa Major and the lowest close to the horizon. There was a slight magnetic disturbance. At 3 a.m. a somewhat sinuous arched band (brightness 1 to 2) extended from a point in Hercules in NNW., through Lyra, Draco, Boötes, Canes Venatici, Ursa Major, Leo Minor, and Leo, ending in the clouds in the E. At 3.15 it was slightly higher and was developing into a zone of several bands. At 4 a.m. there was a regular narrow arch (brightness 1) from α Lyra to α Leonis, the crown passing close to η Ursa Minoris, and a broad, hazy band (brightness 1) in the NW., through Cygnus, Cepheus, Draco, and Ursa Minor, ending in Camelopardalis. The whole had faded to traces at 4.15.—5 a.m. showed only faint traces in the NE., and traces were also observed at 10.10 and 12.10 p. m.—At 1.12 p. m. there was a quiet yellowish and white band from Gemini through Ursa Minor and Cygnus, and a few streamers through Lacerta (brightness 0 to 1). The last faint traces were seen at 2 p. m. in Cassiopeia and Lacerta. Besides the disturbance already mentioned there was slight disturbance at 8, 9, and 11 a. m.

December 24, 1882, 1.15 a. m. to 10.10 a. m.—At 1.15 there was a hazy band (brightness 0 to 1) from Hercules through Corona Borealis, Boötes, Ursa Major, Lynx, and Gemini, quickly fading and appearing again. It was invisible at 2, but well developed at 2.15, and passing through the same constellations in the N., but a little higher, and through Cancer instead of Gemini to Canis Minor. At 3 there was a bazy band (brightness 0 to 1) up through Cygnus in the NW., Cepheus, Cassiopeia, and Perseus, ending in Auriga, and a trace in Monoceros in the ESE. At 3.15 the whole was very faint and the main band had risen a degree or two. At 4 there was a broad, rather hazy belt in the NE. (brightness 1) from Boötes to Leo, and a quiet, regular arch in the SW. from the lower part of Pegasus to Orion's Belt. This arch still remained at 4.15, but the eastern belt had faded to a trace. Across the zenith, from Cygnus to Auriga, was a broad, convoluted band, with considerable withing and twisting motion. There was a slight magnetic disturbance. At 5 a. m. there were faint, motionless bands, yellowish green (brightness 1), from Orion, through Canis Minor, to Leo, and from Leo to Ursa Major and to Draco, and from Draco, through Cygnus, Lacerta, and Andromeda, to Pisces. Traces were seen at 8 and again at 10.10 a. m. In addition to the disturbance already mentioned there was quite a considerable one from 8 to 11 a. m.

December 25, 1882, 2 a. m. to 2.15 a. m.—Clouds covered the sky during the greater part of the night, but at 2 a. m. they were sufficiently thin and broken in the N. and NW, to show pale streaks in the NW, streaming up towards the zenith. These streaks were near α Lyræ, which was the only star visible in that part of the heavens. At 2.15 there was a simons streak (brightness 1 to 2) visible through the clouds from near the horizon in the NW, to a point about 10° west of the zenith, where it ended in the clouds. No more aurora was seen. There was a slight magnetic disturbance at 4 a. m. and again at 7 a. m.

December 26 and 27, 1882, 10.15 p. m. to 9.10 a. m.—There was a bunch of scarcely discernible streamers in the NE, at 10.15, and at 11.15 a faint patch in Gemini. At 12.15 a, m, there was merely a faint flush in the NE. At 1 a.m. there was only a portion of a pale (0 to 1) arch lying low in the NE, in Coma Berenices and Leo, and at 1.15 there were also two or three shifting streamers of the same brightness in Boötes and Corona Borealis. At 2 there was a sinuous band (brightness 1) in the NE, from Cancer t'grough Leo, Canes Venatici, Boötes, and Corona Borealis, ending in Hercules in the NNW. At 2.15 it was brighter (1 to 2), and a second band had developed above it through Cancer, Leo, Leo Minor, Canes Venatici, Ursa Major, close to  $\eta$  Boötis, Corona Borealis, and Hercules. Streamers in Hercules stretched from the lower band through the upper. The upper band was observed to break gradually into short streamers, with considerable flickering from the N. to S. There was also a hazy patch (brightness 0 to 1) in Orion and Taurus, SSE. At 3 a. m, a broad zone of the common type crossed from Canis Minor in the SE, to Cygnus below & Cygni in the NW. The western edge, which was the brightest, ran through the head of Orion, Aries, Taurus, Triangulum, as d. Andromeda, the top of Pegasus and Vulpecula, and the eastern, which was very pale west of the zenith, through Gemini (inclosing δ Geminorum), Auriga, Camelopardalis, Ursa Minor, and Cepheus. At 3.15 it had condensed into a single rather broad band in the position of the western edge of the zone (brightness 2 to 3), tinged on the upper edge with green and with rose on the lower. This band was unchanged in position at 4, but was a little paler, and the constellation had set through it a little. It had regained its former brightness at 4.15 and had

risen to the position of the middle of the former zone, while incipient sinuous and convoluted bands were developing in the E. from Hydra through Leo and Coma Berenices. At 5 there were two faint, quiet bands (brightness 1), one through Cygnus, Cassiopeia, Auriga, Gemini, and Caneer, and the other through Leo Minor, Ursa Major, and Draco. At 6 there was a quiet band (brightness 0 to 1) from Canis Minor through Orion, Taurus, and Aries. At 7 there were traces of a faint band from the W. to NW., and at 8 faint traces in the SW. The last traces were seen at 9.10 a.m. The magnetic needles were practically undisturbed all night.

December 27 and 28, 10.15 p, m, to 9.10 p, m,  $\rightarrow$  At 10.15 p, m, there was an arch in the NE, with its curve at a Geminorum, altitude about 30°, and extremities being NNW, to SE, passing through Taurus, Gemini, Lynx, Leo Minor, and Coma Berenices. It was narrow, except in Coma Berenices, where it was broken into 5 streamers. At 11.15 there was a band like a half arch, passing through Gemini, Leo Minor, Coma Berenices, and Boötes (brightness 1), and a faint streak from Cygnus to Cassiopeia. At 12.15 a. m. there was an arch in the NE. through Orion, Gemini, Lynx. Ursa Major, Canes Venatici, and Boötes, very broad in Ursa Major, with streamers in Boötes (brightness 1). This had risen at 1 a. m. into a broad zone (brightness 1), with its bands very sinuous and broken and in motion across the zenith from the NNW, to the ESE,, the extremities rising from the haze. The western edge ran through Orion, Taurus, Andromeda, Pegasus, and Cygnus, and the eastern through Gemini and Ursa Major. At 1.15 it was quieter and narrower, being confined to the part west of the zenith. The aurora was still in the form of a zone at 2 a. m., with its starting points in Monoceros ESE, and Hercules NNW, It consisted of three main bands. The western and brightest (brightness 1 to 2) band was in rapid waving motion, and ran through Orion, Taurus (not inclosing the Hyades or Pleiades), Persens, Cassioneia, Cepheus, close to δ Cygni and Lyra, the eastern barely reaching Gemini and Ursa Major. At 2.15 it was quieter and spread about 15° each way. At 3 the zone still continued (brightness 1 to 2), with its starting points in Monoceros ESE, and Aquila NNW., stretching west to the square of Pegasus and east to Canes Venatici, with additional bands in the NE. through Leo, Coma Berenices, and Boötes. It was quiet and brightest in Cygnus. At 3.15 it was in the same position but paler (brightness 0 to 1); 4 a. m. showed only traces of the extreme east and west bands, but at 4.15 the eastern traces had developed into convoluted bands (brightness 1) through Leo, Coma Berenices, Boötes, and Corona Borealis. At 5 there were only traces over the horizon from NW, to SE. At 6 there were two motionless bands (brightness 1), one through Pegasus, Perseus, Cassiopeia, Camelopardalis, and Lynx, and a short band from Ursa Major to Boötes, At 7 a, m. there was a band (brightness 0 to 1) from Pisces through Aries, the Pleiades, and Orion through Canis Minor, At 8, 9, 10, and 10,10 a, m, there were still faint traces. The horizontal force read high during the early part of the evening, and was somewhat agitated at 2 and 3 a. m., while at 6 and 7 there was a lively disturbance, the force falling too low to be read. The other elements were slightly or not at all affected,

December 28 and 29, 1832, 11.10 p. m. to 2.12 p. m.—Though the sky was completely covered with clouds at 11.10 p. m., bands of aurora, which must have been very bright, appeared across the zenith from NW, to SE, in rapid sinvous motion. At 2 a, m, the sky was partially clear, and broad diverging bands (brightness 1), radiating from Cygnus in NW., stretched across zenith towards the SE, At 2.15 a bank of clouds about 15° high lay along the western horizon, and above this nearly to the zenith the sky was covered with almost parallel broad bands from the NW, to the SW. The lowest resting on the banks of clouds was the brightest (brightness 2 in NW.), and the highest brightness (1) ran through Cygnus, Cassiopeia, and Leo, ending in the clouds. At 3 portions of bright bands could be seen through the clouds in the NW, and SE, at an altitude of about 40° At 3.15 a broad bright band could be seen across the zenith from NW to SE, through the hazy clouds. At 4 there were broad hazy bands across the zenith from NW, to SE, apparently in motion, but much obseured by haze, and also a brighter band lower in the W. All was obscured by haze at 4.15 except traces of the last band. No more was seen till 7, when the clouds partially cleared again, and a broad band (brightness 0 to 1), and motionless, through Lyra, Corona Borealis, Boötes, and Coma Berenices, was visible. At 8 the sky was wholly clear, and two or three bands (brightness 1 to 2), with streamers, some of them reaching the zenith and all vibrating rapidly from W. to E. Their color was yellowish, and they occupied Taurus, Orion, Auriga, Camelopardalis, Gemini, Lynx, Leo, duted bands re were two Cancer, and (brightness a faint band 0 a.m. The

and Hydra. There were a few traces in the NW, and E. at 9.15. The 10.15 observation showed aluminous patch (brightness 0 to 1) in Taurus in the NW, horizon, and extending through Auriga, and another similar patch in Cygnus. At 11.10 a narrow white band (brightness 1) extended from the SE, to the W., with its crown at an altitude of about 20°, its western end being somewhat broader. A white, quiet band also extended from the horizon SW, to Polaris. At 12.17 p. a. there was an aurora reaching the horizon in the NE, and W. (brightness 1), white and quiet. At 1 p. m. there was a zone of the usual type, with its starting points NNW, and SSE, starting from Lacerta and reaching to Leo Minor. This was reduced to traces at 1.12, and faint traces were still discernible at 2.15. A magnetic disturbance began at about 2 a. m. and reached its maximum at 8 a. m., the horizontal force falling too low to be read, and the eastern declination increasing over a degree. The disturbance was large again at 1 p. m.

December 19 and 30, 1882, 10.15 p.m. to 3 p.m.— At 10.15 p.m. there was a low arch (brightness 1), with its extremities bearing E. by S. and N. by W., passing through Orion, Gemini, Lynx, and Leo Minor, and faint recurved streamers in Coma Berenices and Canes Venatici. At 11.15 the arch was irregular and waving (brightness 2), and passed through Orion, Gemini, Leo Minor, Lynx, Coma Berenices, and Boötes. At 12.12 a, m, there was an irregular and waving arch, very low in the NE., through Canis Minor, Leo, Coma Berenices, and Boötes, with a few faint streamers in Boötes (brightness 1). The arch had risen at 1 into a broad zone, with its starting points in Hercules in the NNW, and Monoceros in the ESE. The western band (brightness 1) crossed through Cassiopeia, but faded before reaching Monoceros. The next band only reached Ursa Major, while the eastern. which was the brightest (brightness 2) and yellowish in color, passed through Corona Borealis, Boötes, Canes Venatici, Leo Minor, and Cancer, and there were also below this two or three paler partial bands. At 1.15 the whole had faded to traces except the band in the E., which now ran through Leo. At 2 a.m. there was an arched band in the same place (byightness 1) and a streamer from the NNW., and reaching into Lyra. This streamer was gone at 2.15, the band was paler, and there was a streamer in the ESE. From 2 to 3.15 there was a broad zone (brightness 0 to 1) of hazy bands, broad and somewhat shifting. The starting points were in Hercules in the NNW, and a line in Monoceros and Hydra from the SE, to the ESE,, and the sky was covered by the zone between Leo in the NE, and the lower part of Pegasus in the SW., except between the zenith and Ursa Major. At 4 the zone had nearly all faded except the eastern band and another about 20° broad through Cassiopeia. This had shifted westward into Perseus and Andromeda at 4.15, and was fading rapidly. At 6 there was a motionless band (brightness 2) in the SW, through Canis Minor, Cancer, Gemini, Orion, Taurus, and Pisces. At 6 a. m. an extensive zone (brightness 4 to 2) covered the sky. The starting points were in Pegasus WNW, and Leo ESE, the edges running through Aries, Gemini, Coma Berenices, Boötes, Corona Borealis, Lyux, Cygnus, and Lacerta. There was a slow waving motion, and some of the bands were broken into streamers. At 7 there was a faint band (brightness 0 to 1) through Delphinus, Hercules, and Boötes. At 8 a band (brightness 2 to 3) with streamers in rapid motion, colors changing from yellow to green and red. ran through Triangulum, Aries, Taurus, Perseus, Auriga, Gemini, and Leo. At 9.10 there was a bright patch in the E, and NE, at an altitude of about 20°, with long faint streamers extending to Polaris. It was white and quiet (brightness 2). At 10 there were a few faint traces, but no more was seen till 1 p. m., when the aurora revived as a sigmoid band (brightness 0 to 1) extending from Leo Minor in the SW, to Boötes in the S. A twisted band ran through Ursa Major from Gemini to Hercules, while a crown of the same brightness, fading very rapidly, was found in Ursa Minor. At 2 there was a broad band (brightness 0 to 1) in the NE., through Cygnus, Perseus, Lacerta, and Auriga, and faint traces of coronal streamers and of streamers in the SW. The last faint traces were still visible in the NE, at 3 p. m. The hor izontal force instrument was agitated between 2 and 4 a. m., and there was considerable disturbance, chiefly affecting the horizontal force, from 8 a, m, to 3 p, m,

December 30 and 31, 1882, 10.15 p. m. to 2 p. m.—The aurora began at 10.15, with a flush in the NE., continuing but little changed at 11.15. At 12.15 a. m. it had developed into a definite though pale band, through Gemini, Leo Minor, and Canes Venatici. From 1 to 1.15 the eastern horizon was much obscured by haze, and there was a regular but rather narrow arch in the NE., with its crown apparently in Coma Berenices, at an altitude of about 25°, with its extremities about N.

H. Ex. 44----52

and ESE. At 2 the horizon was still obscured and the arch was higher and brighter (brightness 1 to 2) with its extremities ESE, (observed to be near Regulus) and NNW. There was also a broad forked hazy band (brightness 0 to 1) from the NNW, end up through Lyra and Cepheus. The arch only remained at 2.15. At 3 the arch was somewhat irregular (brightness 1) from the ESE, to the NNW, passing through Leo, Leo Minor, Ursa Major, Draco, and Lyra to Aquila. At 3.15 if was brighter (brightness 1 to 2) and an additional band (brightness 0 to 1) through Ursa Minor connected it into a zone. At 4 a. m. there was a broad hazy zone (brightness 0 to 1). with its starting points in Hydra ESE, and Aquila NNW, passing through Caucer, Gemini, Anriga, Persens, Cassiopeia, Andromeda, Pegasus, and Lacerta, and a band (brightness 1 to 2) in the NE, from starting points through Leo, Coma Berenices, Boötes, Corona Borealis, Hercules, and Serpens. This band was in the same place, but the zone was farther E. and narrower and passed through Ursa Major and Ursa Minor. At 5 a. m. a quiet yellowish band (brightness 1) passed from Pisces through Taurus, Orion, and Monoceros. At 6 there was a band (brightness 1) waving slightly from W. to E. through Aries, Taurus, Gemini, and Canis Minor. There were faint traces at 7 and 8. also at 10.10 and 12.10. There was a demite aurora at 1 again; a narrow band (brightness 0 to 1) passing between Gemini and Auriga, through Ursa Minor to Cygnus in the ESE. Faint traces were still visible in the NW, and in Cassiopeia at 2 p. m. There was a disturbance, not very great, with decrease of horizontal force and increase of the other elements at 7 to 8 a.m., and again much less violent at 1 to 2 p. m.

December 13, 1882, January 1, 1883, 10.15 p. m. to 12.17 p. m.—At 10.15 there were faint bands surmounted by very faint streamers in the NE., passing through Gemini, Lynx, and Leo Minor, This had faded at 11.15 to a more hazy streak just above the NE, horizon, with its extremities bearing N. by W. and E. This disappeared again before the next observation; was beginning to develop again at 1 a.m. At 2 there were three faint, ill-defined arches (brightness 0 to 1) in the NE., from Hercules to Leo, through Corona Borealis, Boötes, and Coma Berenices, with a faint streamer running up into Draco at the NNW, end. There were three or four additional streamers in the same place at 2.15. At 2 the arches had risen and become a broad hazy zone (brightness, 0 to 1), brightest on the edges, with its starting points in Hydra ESE, and Aquila NNW. The highest point of the eastery edge passed through the top of Canes Venatici and of the western through the lowest part of Andromeda. This zone lasted two hours, with its starting points having the same bearing, of course changing its relations to the constellations as they moved through it, and its band carying slowly in brightness (from 0 to 1 to 1 to 2) and position. At a there were two bands (brightness 1 to 2), one short with streamers on the western end, and a long one below it with streamers in the E., vibrating slowly from W. to E., running through Pegasus, Lacerta, Cygnus, Lyra, Draco Corona Borealis, Boötes, and Coma Berenices. At 6 a quiet band (brightness 0 to 1) ran from Pegasus to Hercules and Boötes. A similar but brightness 1) band at 7 a. m. passed through Canis Minor, Orion, Taurus, Aries, and Pisces. At 8 a. m. a comparatively narrow zone (brightness 1 to 2) crossed the zenith from Pegasus to Leo Minor, through Cassiopeia, Ursa Major, and Ursa Minor. There were besides two bands S, of the zenith from Leo to Andromeda through Cancer, Gemini, Auriga, and Perseus, with several patches of streamers between the bands vibrating rapidly, and a few beams of light from Ursa Major towards the S. (brightness 1 to 2). At 9.17 there was a broad band (brightness 1 to 2) from the SE, to NW., with a smaller band meeting it at its SE., and in Canis Minor in the W., about 5° apart in the middle, with white and quiet streamers above and from the smaller band extending towards the zenith. Traces of aurora continued visible till 12.17 p. m. The magnetic needles were remarkably quiet up to 4 a. m., when there was a slight disturbance, lasting over two observations—a decrease of all three elements. They again became quiet at S a. m., the horizontal force suddenly fell too low to read, and gradually recovering itself during the next two observations, while the other elements were almost undisturbed, both rising slightly.

January 1 and 2, 1883, 10 p. m. to 7 a. m.—At 10 p. m. there was a patch of aurora in the NE, in Cancer and Leo Minor, forming an irregular arch, with ill-defined streamers. This had wholly disappeared in ten minutes. At 11.15 there was an example of a new form of aurora, two arches arranged longitudinally, one narrow and rather irregular from Boötes through Coma Berenices. Leo, and Cancer to Canis Minor, reaching an altitude of about 15° in the NE,, and the second

brightness was also a 1 Cepheus, 1) from the to Aquila, rough Ursa ss 0 to 1), ar, Gemini, ss 1 to 2) in reules, and and passed from ing slightly is at 7 and 8, thess 0 to 1)

paler and lower from Canis Minor to Orion's belt. At 1 a. m., there was a very faint arch (brightness 0 to 1) in the NE., with an altitude of about 10°, through Leo, Coma Berenices, and Boötes. Beneath was a well-defined dark segment. No more was seen till 4.17 a. m., when there was a band (brightness 0 to 1) from N. to E. through Coma Berenices and Corona Borealis. At 5.17 a yellowish-green band (brightness 1) ran from Cygnus through Lyra, Hereules, and Boötes. Faint traces were observed at 7 a.m., while clouds prevented observation during the rest of the night. The magnetic needles were comparatively undisturbed up to about 7 a. m., when a considerable disturbance began, which was still going on after daylight.

January 3, 1883, 3 a. m. 40 11.15 a. m.—A bank of clouds lay along the horizon all the early part of the morning, and above them there seemed to be considerable glow, though no definite aurora was seen till 3 p. m. (8.43 p. m. local time, January 2), when there was a broad hazy band (brightness 1) somewhat sinuous near the horizon, stretching across the zenith from a point in Hydra in the ESE, to Aquila NNW, through Cancer, Lynx, Ursa Minor, Cepheus, Draco, and Cygnus, This band was about three times as broad at 3.15, embracing also part of Gemini, all of Auriga, part of Perseus, all of Camelopardalis, Cassiopeia, and Cepheus, and part of Draco, Lacerta, and Sagitta. At 4 a. m. it had shifted west of Cassiopea, and was much broken, but a band rapidly developed through Cassiopeia from the SE,, waving gently. At 4.15 the whole sky was covered with broad bands winding in large sinuous curves, one especially from Lyra in the N. up to Cassiopeia, then to Aries and the Pleiades and to Auriga. There was a bright, hazy, irrregular patch of large extent in the NW. The brightness of the whole was I, and all shifted slowly, with gentle andulations. The intensity of the magnetic needle had been low for over twelve hours, and the horizontal force needle was now agitated. At 5 it had subsided into two broad, quiet bands, starting from Pegasus (brightness 1), one going S, to Orion, and the other N, to Hercules. At 6 there were only traces of a band from SE, to W., at an altitude of about 45°. At 7 a broad, yellowish-green band waving rapidly from W, to E, (brightness 1 to 2) ran from Pegasus through Andromeda, Cassiopeia, Camelopardalis, Ursa Minor, Ursa Major, and Canes Venatici. No more amora was seen till 11.15 p. m., when there were faint traces in the E. The intensity continued low, being consideraly disturbed at 9 a.m.

January 4, 1883, 3 a. m. to 8 a. m.—At 3 a. m. (10 p. m. local time) there was a very faint vertical streamer about 20° long running from near the horizon ESE. This was prolonged at 3.15 into a narrow band (brightness 0 to 1) from Hydra, through the top of Leo, Leo Minor, and U. Major, then burning very pale through Draco and fading in Lyra W. of a Lyrae. At 4 traces of the band were perceptible a little higher, and at 4.15 the traces crossed the zenith. At 5 a yellowish quiet band (brightness 0 to 1) ran from Cygnus in the NNW, through Lyra, Hercules, Corona Borealis, Boötes, and Coma Berenices. At 6 a. m. a broad, motionless band (brightness 1) extended through Aries, Taurus, Orion, and Canis Minor. After this traces only were noticed in the NE, at 7 and from the NW, to W. at 8. The magnetic intensity continued low, especially the horizontal component, but there was no disturbance.

January 5, 1883, 12.15 a, m, to 5 a, m,—There was a faint glow in the NE, at 12.15 a, m., which had developed at 1.15 into a regular, narrow, quiet arch through the haze in the NE. (brightness 1), with its extremities bearing ESE, and NNW, and its crown at an altitude of about 30°. The stars in the neighborhood were obscured by a bank of haze. There was also a band of the same brightness beginning in a bank of haze in the NNW, and running through Lyra, Draco, Ursa Minor, Camelopardalis close to 3 Auriga and Gemini, fading in a few minutes. At 2 a. m. there were two sets of auroral bands starting from nearly the same place in the haze in the ESE, and NNW., one a broad band, hazy and twisted, waving gently through Lyra, Cygnus, Cassiopeia, Auriga, and the western side of Gemini and Canis Minor, and the other a zone of three or four quiet bands in the NE., the highest through Ursa Major, and the lowest through Leo. The brightness of the whole was 1. At 2.15 the western band was gone, except its NNW, end, and the zone had increased to six or seven bands. At 3 a. m. a very broad hazy zone (brightness 0 to 1) covered nearly the whole of the sky. The starting points were hidden in the ESE, and NNW,, and the castern edge reached the hazy clouds close to the horizon, while the western passed through Cyg nus, Andromeda, Perseus, Taurus, the upper part of Orion, and Monoceros. It was very much faded at 3.15, though the eastern edge was growing bright. At 4 only that part of the zone which was NE. of the zenith remained, very pale and hazy, while at 4.15 it was very much broken and hazy, and traces of the western band were reappearing. The horizontal force was low and agitated. The haze and clouds continued increasing, and a few faint traces were seen at 5 a. m. The needles were hardly disturbed all night, though the intensity was comparatively low, much higher, however, than for the last twenty-four hours.

January 5 and 6, 1883, 10.15 p. m. to 2 p. m.—Flashes and streamers, very pale, began to appear in the NE, about 4.30 p. m. local time (9.15 Washington time), and at 10.15 had developed into a band of short bunches of streamers extending from the N. to E. through Orion, Gemini, Lynx, and Ursa Major (brightness 1). This soon disappeared, and no more was seen, the sky being partially ob. scured by haze till 2 a. m., when there was a motionless narrow band across the zenith (brightness 0 to 1) visible through the haze from the NNW, to ESE, near Gemini. This was wholly visible at 2.15. Several bands showed through the clouds at 3 a. m., one in particular in the NE, (bright, ness 2) at an altitude of about 40°. At 3.15 the band had reached an altitude of about 60° and the whole sky round the zenith was covered with waving bands. The sky then became completely obscured, only clearing partially at 8 a.m., when yellowish bands (brightness 0 to 1), waving slowly and partly hidden by clouds, were visible, running from Ursa Major through Auriga, Perseus, and Aries. The sky rapidly cleared at 9.17, and there was a quiet white band (brightness 0 to 1) near the southern horizon, running E. and W., sending up streaming patches through Leo and Coma Berenices, and at the W. end in and near Canis Minor. The aurora was unchanged at 10.17 except for additional patches in the N. in Triangulum, Pegasus, and Audromeda. Traces only were seen the next two hours. At 1 p. m. there were two bands (brightness 0 to 1) from Boötes to Cygnus, through Corona Borealis and Hercules, and a band through Ursa Major, Ursa Minor. Cepheus, and Cygnus. The last traces were seen at 2 p. m. close to the zenith and near Cassi. opeia. The horizontal force was unusually high about an hour before the aurora began, and a disturbance commenced at 4 a. m. lasting about twelve hours. It reached its maximum at 9 a. m. and had a second period of violence at 2 p. m., the horizontal force being most affected both times and falling low.

January 7, 1883, 12.15 a, m, to 11.17 a, m,—The weather was cloudy early in the evening, but the clouds began to break away at about 7 p. m. local time (12 midnight Washington); an auror. light was visible through the clouds in the NE. At I a. m. a zone (brightness I), and much opseured by the now breaking clouds, was observed passing about 15° west of the zenith from NW. to SE. At 1.15 the zone was more broken into separate bands, and the middle band, which was brightest, was observed to pass through Cygnus, Cassiopeia, Perseus, and Orion. The sky was rapidly clearing at 2, but the aurora was still much obscured. It appeared to be the same general form, but much broader and brighter, one bright streak in particular (brightness 2 to 3) across the zenith. At 2.15 the zone had sunk towards the NE, still hidden in the bank of clouds, with an altitude of about 60°. There was also a bright patch showing through the clouds in the NNW, close to the horizon. The sky was clear at 3, and starting from Aquila low in the NNW, came a broad band across zenith through Cygnus, Cepheus, Ursa Minor, Camelopardalis, and ending in Gemini (brightness 1), much twisted near the zenith, and a hazy band through Corona Borealis, and ending in a bright patch (1 to 2) in Boötes in the NE. At 3.15 there were four rather broad arched bands across the eastern sky, starting from the same place in the NNW, and ending in the clouds in the SE, near Leo, the highest through Ursa Minor and the lowest close to the horizon. These, however, only lasted a few minutes. At 4 the zone was very broad and consisted of three widely separated bands, broad and hazy (brightness 0 to 1); the starting points were close to a Hydra in the ESE, and  $\alpha$  Aquila in the NNW. The western band was narrow, and ran through Orion and the lower part of the square of Pegasus; the middle was broader and ran through Cygnus, Cepheus, Cassiopeia, Cameleopardalis, Gemini, and Cancer; and the eastern ran through Lyra and Ursa Major, going no farther than Leo. At 4.15 the middle and eastern bands were brighter (brightness 1), and the middle band had moved about 5° west. At 5 a. m. the whole sky was covered with bands running from Pegasus in the NNW, to Leo in the ESE,, the SW, edge being in Aries, Taurus, Orion, and Canis Minor, and the NW. in Coma Berenices, Boötes, Corona Borealis, Lyra, Cygnus, and Lacerta. The SW, half was quiet (brightness 1) with confluent bands, but in the NE, half there were several bands of streamers approaching the curtain form and vibrating h broken and low and agiat 5 a.m. The much higher,

gan to appear ed into a band ynx, and Ursa partially ob. th (brightness olly visible at NE. (bright. about 600 and me completely to 1), waving a Auriga, Perd (brightness s through Leo unchanged at neda. Traces 1) from Boötes , Ursa Minor, id near Cassigan, and a disum at 9 a. m.,

Only a few traces overhead were left at 6, and for the next three hours the sky was clouded over, though there were traces in the S. at 8. It was clear again at 10.17, and an irregular white quiet band was seen running from SE, to NW., through Draco, Ursa Major, and Canes Venatici. There was a broad streamer in Lyra in the E. about 30° long, and a bright patch in the NW. in Triangulum, Aries, Taurus, and Perseus. At 11.17 the SW, half of the sky was covered with white quiet bands converging in the E. and W. (brightness 0 to 1), and there were also streamers from Sagitta and Cygnus in the NE, to Triangulum in the NW. This was accompanied by a violent disturbance, the horizontal force being too low to read, and the declination rising over two degrees, with large increase of the vertical component of the force. The display at 5 was accompanied by a disturbance affecting chiefly the horizontal force. After 11.17 the sky became permanently cloudy.

January 7 and 8, 1883, 10.15 p. m. to 7 a. m.—At 10,15 there was an arch of fine short streamers in the NE, with its extremities bearing NW, by NE, by S., and an altitude of about 30°. This faded, and none was seen till 12.15 a.m., when there was a zone, with its starting points in Orion and Serpens. Of these bands two were close together and parallel, passing nearly overhead, and the third through Serpens, Hercules, Cygnus, and Pegasus; thence to Orion it was broken into streamers. In Serpens and Boötes the band had the curtain form (brightness 1). The zone form continued at 1 a. m. (brightness 1), with its starting points in Monoceros ESE, and Hercules NNW. The main portion (three bands, two narrow and one broad, considerably twisted) ran through Lyra, Draco, Cepheus, Ursa Minor, Camelopardalis, Auriga, Gemini, and Canis Minor, and a paler band passed through Canis Minor, Lynx, and Ursa Major, then fading towards the N. This eastern band was brightest at 1.15. At 2 the starting points of the zone were just below a Leonis E. by S. and near 7 Aguille NNW. From a Leonis to Monoceros ESE, it was horizontal, and the eastern edge then passed through Cancer, Gemini, Auriga, Camelopardalis, Ursa Minor (W. of Polaris), Cepheus, Draco, and Cygnus, and the western through Canis Minor, Orion, Taurus, Aries, Triangulum, Andromeda, Pegasus, Vulpecula, and Sagitta (brightness 1 to 2). The horizontal portion was gone at 2.15. At 3 a, m, bands and streamers (brightness 1) approaching the curtain form, especially in Leo, filled the NE, sky from Leo ESE, to Hercules NNW, and from near the horizon to Ursa Major. This was broken and paler at 3.15 and a pale streamer was shooting up from the NNW, ending in Cassiopeia. The sky was half overcast with hazy clouds at 4, and at 4.15 traces were visible through the clouds in the N. At 5 there was a pale yellowish band (brightness 1) in the SW, from Monoceros and Canis Minor through Orion, Taurus, and Aries The sky then became more cloudy and traces only were observed in the S. at 6 a. m., and in the NE. at 7 a. m. The sky then became wholly obscured. The magnetic needles were comparatively quiet, being slightly disturbed from 3 to 8 a.m. and again from 12 m. to 2 p. m.

January 8 and 9, 1883, 10 p. m. to 2.12 p. m.—There was a glow in the NE, at 10 p. m. which at 10.15 had developed into a faint arch, with its extremities bearing N. and E. and its crown at an altitude of about 20%. This was gone at 11, but at 12.15 a.m. there was a patch of hazy light in the N. in Canes Venatici, Coma Berenices, and Ursa Major, and a line of faint streamers through Corona Borealis, Boötes, Ursa Major, and Lynx. At 1 there was a slightly sinuous arched band (brightness 4) in the NE, from Monoceros ESE, through Canis Minor, Cancer, the top of Leo, Leo Minor, the lower part of Ursa Major, Canes Venatici, Boötes, and Corona Borealis to Hercules in the NNW. The northern end appeared to be breaking into streamers. These had developed at 1.15 into a bunch shooting up into Draco, and the band had split into two. At 2 a. m. these started from Hercules in the NNW., three or four diverging bands stretching across the eastern sky growing paler towards the SE.; one through Lyra, Ursa Minor, Ursa Major, and Lynx; one through Corona Borealis, Boötes, Canes Venatici, Leo Minor, and Leo, and one or two between this and the horizon with traces of a band which was developed at 2.15 through Cygnus, Cepheus, Cassiopeia, Camelopardalis, and Auriga to Gemini, while the eastern bands were fading. The sky then became overcast. Traces of a zone across the zenith were visible through the hazy clouds at 3, and similar traces of a band at 4 a. m., which appeared to be moving W. Traces were seen again in the NE, at 6 a.m. The sky was partially clear at 8.17, and a quiet band (brightness 1) ran from Andromeda through Lacerta, Cygnus, Draco, and Boötes. The sky cleared off permanently after this. At 9.17 there was a broad, quiet, white band (brightness 1) along the southern horizon

from E. to NNW, and a similar band from SE, horizon through Leo to Canis Minor. A third parrower band, ran from E. to W. close to Ursa Major. There were faint streamers in Labor Cygnus, Lacerta, and Cassiopeia, also S. in Boötes, Coma Berenices, and Leo Minor, faint, when and onict. There were bright (brightness 2) streamers in the W. and NW. in Taurus, Pleinh. Persons, and Auriga. They were rose-colored and vibrating rapidly. At 10.17 there was a broad faint white band on the southern horizon, and a band across the zenith SE, to NW., white and quiet (brightness 0 to 1). At 11.17 there was a broad, quiet, white arch (brightness 0 to 1) is an E. to W., through Corona Borealis, Ursa Major, and Gemini. At 12.17 p. m. there were 3 such bands, one through Polaris and the lowest at an altitude of about 45°. At I p. m. these bands (brightness 0 to 1) started together from Gemini and ran as follows: One, the broadest and brightest, through Leo Minor, Boötes, Corona Borealis, and Hercules; one through Ursa Major, Draco, and Cygnus, and one through Ursa Minor to Cygnus. These bands were constant. shitting, rising towards the zenith and then receding sout', ward. The last traces were seen near the zenith at 2.12 p. m. The magnetic needles were quiet up to 9 a. m., when the horizontal force began to fail, culminating in a disturbance at 1 p. m., with very low horizontal force, high easter; declination, and almost undisturbed vertical intensity.

January 9 and 10, 11,15 p. m. to 1 p. m.—At 11,15 there was a hazy light in the NE, which of veloped into a faint pale arch, and faded completely before midnight. At 1 a. m. there was a pale glow in the NE. At 2 there was an extraordinary zone parallel to the magnetic meridian instead of at right angles to it as usual. It was so pale as to be scarcely perceptible. The starting points were in Coma Berenices NE, and Pisces SW, extending in breadth from the lower part of Draco to a Tauri. At 2.15 there was an arch in the NE. (brightness 1), across the base of the zone, through Leo, Ursa Major, Cames Venatici (including) a Boötis, Corona Borealis, and into Herenics. The sky then suddenly clouded over and remained cloudy until 6, when it cleared, and there was a faint band (brightness 0 to 1) from Boötes through Corona Borealis, Lyra, and Cygnus, and another from Pegasus and Andromeda to Cassiopeia. At 7 there was a quiet, bright band from Leo through Cancer, Genaini, Orion, and Taurus. The sky then became again overcast, and continued so until 12.10 when it was clear, and a few faint traces were observed near the zenith. At 1 the last faint traces were seen in the S. in Boötes and Canes Venatici. The magnetic needles were comparatively quiet all night.

January 10 and 11, 10.15 p. m. to 7 a. m.—At 10.15 p. m. there was a faint band of light in the NE. nearly parallel to the horizon and about 20° above it. At 11.15 this had developed into a low arch (brightness 1) with its extremities bearing NNW, and ESE, passing through Canis Minor, Cancer, Leo, Coma Berenices, and Boötes, sending up streamers in Boötes. The altitude of the crown of the arch was about 15°. At 12.15 a. m. it was reduced to a few very faint streamers in the NE. At 1 there was a very faint arched segment in the SW. There was a similar trace in the west at 2, also in the SE, at 2.15. At 3 there was a pale glow fading insensibly into the sky with a well-defined dark segment below it, lying close to the horizon, from E, to SSW. At 3.15 the whole sky appeared to be covered by the palest possible broad bands, separated by narrow dark spaces, parallel to the magnetis meridian and appearing to converge in the NE, and SW. There were slight traces at 4. At 5 a pale, yellowish band (brightness 0 to 1) ran through Boötes, Corona Borealis, Hercules, and Lyra to Sagitta. At 6 there were mere traces in the N., but at 7 a broad, quiet band stretched from Pegasus through Andromeda, Cassiopeia, Ursa Minor, Ursa Major, and Canes Venatici. This was the last seen. The magnetic needles were unusually quiet.

January 12, 1883, 1 a. m. to 1 p. m.—At 1 a. m. there was a quiet, regular, and narrow area (brightness 1) from the ESE, in Monoceros to the NNW, in Serpens, through Leo (a Leonis), Leo Minor, Ursa Major, just above a Canum Venaticorum, Boötes, and Corona Borealis. At 1.15 it was broader and somewhat sinuous. At 2 there was only a partial arch (brightness 1) from the ESE, in Hydra, through Leo (δ Leonis) and Coma Berenices ending in Boötes at an altitude of about 20°. This was fading at 2.15. At 3 and 4 the western horizon was obscured by haze, and traces only were visible. No aurora was seen at 5, but at 6 a quiet band (brightness 1) stretched from Andromeda, through Perseus, Auriga, Gemini, Cancer, and Leo. At 7 a similar band can through Cygnus, Lyra, Draco, Ursa Major, and Leo. At 8 there were simply traces in the N. At 10.10 there were traces in the E. and SE, and again at 11.10 in the NE. At 12.10 there was a

nor. A third, mers in Lyra, r, faint, who r, faint, who rirus, Pleiade r, was a broad W., white and sse were 3 such to these bands broadest and r Ursa Major, et e constantly were seen near orizontal force

At 3.15 ed by narrow NE, and SW. rough Boötes. e N., but at 7 Minor, Ursa usually quiet. narrow area "Leonis), Leo s. At 1.15 it ss 1) from the in altitude of by haze, and s 1) stretched ilar band ran n the N. At there was a white, quiet arch from E. to. W. through Corona Borealis, Canes Venatici, Ursa Major, Lyny, Gemini, and Canis Minor, and streamers in the E. and NE. (brightness 0 to 1). At 1 p. m. there was a band in the SW. (brightness 0 to 1) from Boötes through Coma Berenices to Leo Minor. This disappeared in a few minutes. There was a slight disturbance at 1 p. m.

January 13, 1883, 8 a. m. to 12.17 p. m.—There were faint traces of auroral light all round the horizon all the early part of the night, but no definite aurora till the 8 a.m. observation (quarter of 3 a.m., local time). There was then a quiet, yellowish band (brightness 0 to 1) from Taurus through Auriga, Gemini, and Lynx. At 9.17 there was a broad arch, white and quiet (brightness 0 to 1) from the ESE, to the W., with its crown at an altitude of about 20%, and a luminous patch similar in color and brightness in Corona Borealis. At 10.17 the arch had risen to an altitude of 35°, and faint luminous patches appeared between the arch and the horizon. At the same time there was a semi-corona of long, narrow, quiet streamers (brightness 2) which reached from the SE, extremity of the arch to Auriga in the W., and from Andromeda to a point near the zenith. This faded in a few minutes, leaving only the arch. At 41.17 a broad, irregular band, formed of patches of white, quiet light extended along the southern horizon from ESE, to W. There was also a narrow, quiet, white arch (brightness 0 to 1) from the E. to NNW, through Sagitta, Vulpecula, Lacerta, Andromeda, Triangulum, Aries, and the Pleiades. From the northern end of the arch streamers extended up through Perseus. At 12.17 p. m. there were three pale white, striated, parallel bands running from the ESE, to the W., the lower, narrow, through Bootes and Coma Perenices; the middle, broad, through Leo Minor and Canes Venatici to Hevcules, and the upper band from the ESE, through Lyra, Draco, Ursa Major, Leo Minor, and Cancer. Paint streamers filled the space between the southern horizon and the lower band. There was also a white, quiet, semi-corona (brightness 1) extending from Lyra though Cygnus, Cepheus, Cassiopeia, and Camelopardalis to Ursa Major. This was all gone at 1 p. m. There was a slight disturbance of the magnetic instruments at 11 a. m. and 12 m.

January 14, 1883, 2,15 a, m, to 1,17 n, m,—Faint, indefinite light, probably auroral, was visible in the Encelose to the horizon, as soon as the twilight disappeared, but the first definite aurora west noticed at 2.15 a.m. (about 9 p. m. local), having developed since the 2 a.m. observation. It was a rather narrow, arched band (brightness 0 to 1) in the NE, from the NNW, in Hereules near herizon to the E. by S. in Cancer, through Lyra, Hereules, Draco, Ursa Major, Leo Minor, and Let (a Leonis), with a short broader band shooting up from the NNW, end through Cygnus. At 3 a. m. a rather broad sinuous band (brightness 2) extended from the ESE, in Hydra to the NNW, in Aquila, passing W. of the zenith, through Canis Minor, Gemini, Auriga, Perseus, Andromeda, Lacerta, Cygnus, and Vulpecula. It was fading slightly at 3.15, and had drifted W., now passing through Monoceros, Canis Minor, Orion, Taurus (: Tauri and Pleiades), Aries, Andromeda, Pegasus (¿Pegasi), and Delphinus. At 4 a. m. there was a rather broad zone. The middle portion was the brightest (brightness 2), and was made up of narrow, twisted streaks, and the edges of about the same breadth were paler (brightness 1). The starting points were ESE, in Hydra and NNW, in Pegasus. The eastern edge passed through Leo, Leo Minor, Ursa Major, Ursa Minor, Cepheus, Andromeda, and Pegasus; the western through Leo, Cancer, Lynx, Auriga, Perseus, Andromeda, and Pegasus. At 4.15 the whole had drifted about 10° westward and was breaking into separate bands and growing paler (brightness 1). At 5 it was reduced to a quiet, yellowish band from Pegasus, through Andromeda, Cassiopeia, Camelopardalis, Ursa Major, Leo Minor, and Leo. At "there was a band in the SW. (brightness 0 to 1), through Pisces, Auriga, Gemini, and Cancer, At 7 a belt of bands (brightness 1) passed through Aries, Taurus, Orion, Gemini, Cancer, Canis Minor, and Hydra. This was reduced at 8 to traces over the southern horizon. At 9 these traces had developed into an arch, spanning the horizon from ESE, to NNW,, with its crown at an altitude of about 15°, white and quiet (brightness 0 to 1). At the same time a broad, irregular arch extended from the ESE., through Corona Borealis, Draco, Cepheus, Cassiopeia, and Perseus, to the Pleiades, in the NNW. It was in rapid whirling and vibratory motion, and at times was tinged with a bright rose color (brightness 4), and lasted but a few moments. At 9.17 there was a very broad arch (brightness 0 to 1) from the ESE, to the NNW., with its corona at an altitude of about 48°, and fringed on the upper edge with very short pale streamers, and at the same time a white, quiet band ran from the E., through Hercules, Lyra, Cygnus, and Lacerta, to Leo. There

was a band in the S, side from Corona Borealis, through Ursa Major, to Gemini, with a slight fringe of streamers, and streamers in the E., N., and W., forming with the band in the S. a well-defined corona. There was no motion except a slight vibration of the streamers in the N. At 10.17 the arch on the southern horizon was still visible, but its streamers had faded. There were faint streamers, quiet and white (brightness 0 to 1), in the NE., in Sagitta and Cygnus, and in the NNW., in Triangulum and Aries. At 11.17 there was a quiet, faint, white arch on the southern horizon from ESE, to WNW. At 12.17 a narrow band (brightness I) extended from ESE, to WNW., through Herenles, Ursa Major, Lynx, and Gemini, with luminous spots also in Cygnus, Lacerta, and Cassiopeia. At I p. m. a band (brightness 0 to 1) ran from Aquila, in the ESE, through Ursa Minor, to Gemini, in the WNW., and the last faint traces were seen at 1.17. The magnetic intensity was slightly increased at 5 a. m., and there was a slight disturbance at 1 to 5 p. m.

January 15, 1883, 5,17 a, m, to 12,17 p, m,—At 5,17 a motionless band (brightness 1) crossed the sky from NW, to ESE,, west of the zenith, through Pegasus, Andromeda, Cassiopeia, Camelo, pardalis, Ursa Major, Leo Minor, and Leo. At 6.17 series of white curtains (brightness 1) with gentle motion covered the sky from the eastern horizon to Auriga and Perseus in the W., and from Leo Minor in the S. to Cygnus in the N. There were also luminous patches in Draco, Pegasus, Triangulum, Aries, and Taurus. At 7.17 yellowish-green bands (brightness 1 to 2), waving slowly trom W. to E., extended from Pegasus through Lacerta, Cygnus, Lyra, Hercules, Corona Borcalis, Brötes, and Coma Berenices. At 8.15 a broad arch spanned the southern horizon from ESE, to W., with its crown at an altitude of about 15. A broad band extended from the western and through Gemini and Leo Minor to Ursa Major, and a narrow irregular band from the ENE, through Cygnus, Lacerta, Andromeda, and then through Cepheus, Cassioneia, and Perseus. The whole was quiet and white. At the next hour there were merely traces in the S, and NW. At 10.17 a white and quiet arch lay over the southern horizon from ESE, to WNW,, with its crown at an altitude of about 15°, with a narrow band from the ESE, through Corona Borealis, Ursa Major, and Gemini. At 11.15 there was a large patch of luminous haze in the S<sub>0</sub> and at 12.17 there was a zone brightness 0 to 1), with its starting points ESE, in Aquila and WNW, in Gemini, extending in breaith from Boötes SSW, to Cassiopeia NNE. Streamers of the same brightness as of the zone ran from Taurus in the NW, up into Perseus. The horizontal force and declination were more or less disturbed from 7 a, m, to 12 m., the force decreasing and the eastern declination increasing.

January 16, 1883, 2.15 a. m. to 7 a. m.—Vague arched bands, which could not with certainty be distinguished from cirro-stratus clouds, were visible at times early in the evening, but there was no definite aurora till 2.15 a. m. (about 9 p. m. local), when there was part of a pale arch in the ESE, in Leo, running from below α to β (brightness 0 to 1). At 3 two croad bands (brightness 1 to 2), nearly straight, slanted up from E. by S. in Leo through Cona Berenices, Boötes above α Boötes, into Corona Borealis. At 3.15 it had changed to a narrow arch (brightness 1) from the E. in Leo through the same constellations, fading in the NNE. At 4 there were only evanescent traces over the southern horizon. At 5 a quiet band (brightness 0 to 1) passed from Cygnus through Lyra, Hercules, and Serpens to Boötes. At 6 there were merely traces in the SE. At 7 a yellowish band (brightness 1) with a few vibrating streamers ran from Pisces through Aries, Taurus, Otion, and Gemini to Cancer. The haziness now increased, and traces only were observed at the next two observations, after which the sky clouded over and the weather became stormy. There was a slight magnetic disturbance at 6 a. m.

January 17, 1883, 9.10 a.m. to 12.17 p.m.—The storm began to break about 9 o'clock p.m., local time. At 9.10 a.m. (Washington time) the sky was clear enough to exhibit a white, quiet arch (brightness 1 to 2) from the ENE, to the NNW., through Sagitta, Vulpecula, Lacerta, Cygnus, and Andromeda to Triangulum, with faint light, partly masked by the clouds in the southern horizon. Traces only were visible at 10, though the sky was clear. The weather then became stormy again, and only traces of the aurora could be observed. Traces of a corona at 11.15 and a few white and quiet traces at 12.17. A disturbance of all three elements commenced at 4 a.m. and lasted till 12 m., reaching to maximum at 11 a.m.

January 18, 1883, 12.15 a. m. to 1.17 p. m.—At 12.15 there was a waving band of curtains (brightness 1) crossing near the zenith from SE, in Canis Minor to NW, in Hercules, through

it, with a slight in the S. a well. in the N. At ed. There were gaus, and in the on the southern d from ESE, to also in Cygnus, la, in the ESE, en at 1.17. The turbance at 1 to

itness 1) crossed Siopeia, Camela. ightness 1) with he W., and from Draco, Pegasus. , waving slowly Corona Boscalis. on from ESD, to the western end ie ENE, through eus. The whole W. At 10.17 a crown at an alri-Ursa Major, and there was a zone ini, extending in ss as of the zone on were more or

on increasing, of with certainty ening, but there pale arch in the ds (brightness I Boötes above a s I) from the E, only evanescented from Cygnus a the SE. At 7 through Aries, y were observed became stormy.

9 o'clock p. m., it a white, quiet a, Lacerta, Cygin the southern r then became ma at 11.15 and enced at 4 a. m.

and of curtains creules, through

themini, Lynn, Ursa Major, Draco, Ursa Minor, and Lyra. At 1 a. m. there was a small zone of two bands in the NE. (brightness 1). The starting points were in Hydra ESE, and Hercules NNW., with the upper band through  $\alpha$  and  $\beta$  Ursae Majoris, and the lower just above  $\alpha$  Canum Venaticum. At 1.15 the zone was condensed to a single rather singuous band (brightness 1 to 2). from the same starting points, running through Leo, Leo Minor, Ursa Major, Canes Venatici, below α Boötis and Corona Borealis At 2 there were two irregular bands in the NE, from the ESE, in Hydra to the NNW, in Aquila, reaching their greatest altitude near a Ursar Majoris, and a shifting band developing from the same starting points through Ursa Minor, At 2.15 the lower bands were in nearly the same place, and the upper band starting below Procyon ran through Gemini, Auriga, Camelopardalis, Cassioneia, Cepheus, and Cygnus (brightness of all 1 to 2). At 3 there was a broad belt of two or three yellow shifting bands (brightness 2 to 3) low in the SW., from NW. in Aquila to SE, in Monoceros, through Pegasus, Triangulum, Aries, Taurus, and Orion, gradually beginning to wave. Traces of these bands still remained in the NW. at 3.15, while a band (brightness 2 to 3) crossed the zenith from NNW, in Aquila to ESE, in Monoceros. North of the zenith the band was composed of short streamers vibrating rapidly from N, to S., and south of the zenith of serpentine streaks waying from S, to N., all shifting rapidly. The lower edge of the band was tinged with rose. At 4 there were only traces in the NE. At 5.15 quiet bands (brightness 0 to 1) ran from Leo through Canes Venatici, Ursa Major, Corona Borcalis, and Hercules. At 6.15 a broad, yellowish band (brightness 1), with streamers moving slightly in Cygnus and Draco, ran through Cygnus, Lyra, Draco, Corona Borealis, Ursa Major, Coma Berenices, Leo, and Leo Minor. At 7.15 there were merely traces in the NE., and none were seen at 8. At 9 and 10 faint traces began to appear, and at 11.15 a white, quiet band (brightness 0 to 1) ran from ENE, to NNW, through Hercules, Draco, Ursa Minor, and Gemini. At 12 a similar band, but broad, ran from the ESE, to NW., through Corona Borealis, Canes Venatici, Leo Minor, Cancer, and Canis Minor, with luminous patches near the southern horizon. The last faint traces were observed at 1 p. m. The magnetic instruments were slightly disturbed from 3 a. m. to 2 p. m., the disturbance reaching its maximum at 1 p. m.

January 19, 3,45 a. m. to 1,25 p. m.—At 3,15 there was a vertical twisted streak in the E., starting in Virgo close to the horizon and running up into Leo, where it blended into two nearly straight bands through Coma Berenices and Boötes, growing pale towards the N. (brightness 1 to 2). The streak waved and shifted slowly. At 4 none was perceptible, but at 4.15 there were faint traces close to the eastern horizon. No more was seen till 7.15, when there were two bands, one from Andromeda through Lacerta, Cygnus, Lyra, Hercules, Corona Borealis, and Boötes, and the other and upper band through Draco and Canes Venatic., waving slowly towards the zenith (brightness 1). There were faint traces over the northern horizon at 8.15. At the next two observations there were faint traces over the southern horizon. At 11,15 a zone of broad bands crossed from ESE, to WNW., white and quiet (brightness 1), covering most of the sky from Boötes in the S. to Cassiopeia in the N. This remained essentially unchanged at the next observation, except that the bands were narrower and more clearly defined. At 1 p. m. a band (brightness 0 to 1) ran from the NW, in Gemini to the E. in Sagitta, through Auriga, Perseus, Triangulum, and Andromeda, and there were faint streamers in Cassiopeia. At 1.17 traces were still visible passing through Cassioneia, but were wholly gone at 1.25. There was a slight disturbance of the magnets, affecting almost wholly the horizontal force, and reaching its maximum about 7 a. m.

January 20, 1883, 2 a. m. to 1.17 p. m.—Arched traces began the aurora lying low in the NE, at 2 a. m. At 3 there was a broad, hazy, and indistinct zone (brightness 0 to 1), which was brightest in the NW, and on the eastern edge. The starting-points were near the horizon, ESE, in Leo, and NNW, in Aquila. The western edge ran through Leo, Lynx, Camelopardalis, Cassiopeia, Cepheus, Cygnus, and Vulpecula, and the eastern through Coma Berenices, Boötes, Corona Borcalis, and Lyra. At 3.15 it had spread a little further west, hazy and indefinite. At 4 there was a rather narrow, regular arched band in the NE, from NNW, in Delphmas to the ESE, in Virgo, through Cygnus, Lyra (α Lyra), Corona Borcalis, Boötes (α Boötis), and Coma Berenices (brightness 1), with two or three incomplete bands below it. This had changed at 4.15 into two broader and more irregular bands, starting from the same points, but reaching a greater altitude, through Cygnus, Lyra, Draco, Boötes, Canes Venatici, and Coma Berenices (brightness 1 to 2). At 5 a quiet band

H. Ex. 44---53

(brightness 0 to 1) ran through Cygnus, Lyra, Draco, Corona Borealis, Boötes, Coma Berenices, and Leo. At 6.15 a similar band (brightness 1) ran through Cygnus, Lyra, Hercules, Boötes, and Virgo, At 7 there were merely traces on the northern horizon. At 8 a quiet double band (brightness 0 to 1) crossed from Ursa Major and Leo to Auriga and Persens. At 9.15 there were faint traces near the zenith and in the ESE, and NW. At 10.15 a. m. a white, quiet arch (brightness 1) ran from the ESE, to the WNW, with its crown at an altitude of about 155, while there were also long, quiet streamers in the E., passing through Corona Borealis, Draco, Hercules, and Lyra, with a luminous bar from Lyra through Cygnus, Cepheus, and Cassiopeia. At 11.15 there was a zone of broad bands (brightness 0 to 1), with its starting-points ESE, and NNW, reaching in breadth from Boötes to the zenith. At 2.15 there was a broad, quiet, white, and diffuse arch from ESE, to WNW. There were also streamers in the ESE, E., and ENE, in Sagitta, Lyra, Aquila, Delphinus, Vulpecula, Cygnus, Pegasus, and Lacerta. The last faint traces were seen in the E. near Aquila and near the zenith. The needles were slightly disturbed at 3 and 4 a. m. with high horizontal force, and from 8 a. m. to 3 p. m, there was a considerable disturbance, reaching its maximum at 11 a. m.

January 20 and 21, 1883, 11.15 p. m. to 11.15 a. m.—The aurora began at 11.15 p. m. as a faint streak in the NE, through Ursa Major, Lynx, and Gemini. At 12.15 a. m. there was a zone of two bands with its starting points W. by N. and E. by S., and passing, one through Canis Minor, Auriga, Cassiopeia, Cepheus, Lyra, and Hercules, the other through Canis Minor, Ursa Minor, Draco, and Hercules (brightness 1 to 2). It was brightest in the W, where the bands assumed the curtain form. At 1 a, m, there was a narrow, arched belt of three bands (brightness 4) from Hercules NNW., starting at an altitude of about 15° to near the horizon ESE, in Hydra, through Corona Borealis, Draco, Boötes, Ursa Major  $(\lambda)$ , and Canes Venatici (above  $\alpha$ ), Leo Minor, Leo, and Cancer. At 1.15 it was a little brighter in the NNW., twisted and spreading into Lyra. At 2 a.m. there was a broad, hazy, indefinite zone (brightness 0 to 1). The starting-points were ESE, in Hydra and NNW, in Aquila, and it extended in breadth from ε Ursæ Majoris to Cassiopeia (near ε). A: 2.15 it was brighter on the edges and spread farther west (into Perseus). At 3 there was a marrow zone (brightness 1) west of the zenith. The starting points were SE, in Hydra and NNW, in Aquila, stretching in breadth from close to Polaris to \alpha Arietis. At 3.15 it was much brighter (brightness 1 to 2) and had drifted W., so that the eastern edge passed through Cassiopeia, and the western took in α Orionis and α Tauri. At 4, three or four bands, broad and sinuoùs (brightness ! to 2), started from Pegasus in the NW., going straight up for about 15°, and then bending round through Cygnus, Lyra, Hercules, Draco, Corona Borealis, and Boötes (a Boötis). At 4.15 twisted streaks (brightness 2) forming a narrow zone from Pegasus NW., through Andromeda, Perseus, Aurig Cemini, Cancer, and Canis Minor, ending in Hydra ESE., with considerable waying motion near the cenith. At 5.15 a band (brightness 1) ran through Andromeda, Lacerta, Cygnus, Lyra, and Hercules. At 6.15 a quiet band (brightness 0 to 1) stretched from Pegasus through Vulnecala and Hercules to Boötes. At 7.15 a zone (brightness 1 to 2) crossed the zenith with its starting-points NW, and SEL, in Aries, Andromeda, Leo, and Canes Venatici. It reached SW, to Gemini and Auriga, and NE, to Corona Borealis and Lyra, where it had a few bands of streamers in rapid, waving motion (brightness 1 to 2). At 8.15 a, m, there were faint traces in the N. Traces appeared again i., the E, at 9.15 a, m, and at 11.15 in the SE. The magnets began to be agreated about 3 a. m. " d were not quiet again till 2 p. m., the disturbance reaching its maximum about 7 a. m.

J. vary 22, 1883, 6.15 a. m. to 11 a. m.—No aurora was seen till 6.15 a. m. (about 1 a. m. local time), when a band passed from Pegasus through Triangulum, Perseus, Cassiopeia, Cepheus, Drace, Ursa Minor, Ursa Major, Boötes, and Coma Berenices to Leo, and Leo Miner, with bright green and yellow streamers in Cassiopeia, Cepheus, and Draco, vibrating rapidly from SW, to NE, and pale streamers waving slowly in SE, (brightness 1 to 2). At 7.15 there was a quiet band (brightness 0 to 1) from Pegasus through Lyra, Hercules, and Corona Borcalis to Boötes. Traces were observed remaining in the N, at 8.15, in the ESE, at 10.15, and in the E, at 11 a. m. The magnets were somewhat disturbed from 6 to 8 a. m., and there was a slight disturbance from 1 to 4 p. m.

January 24, 1883, 9.15 a. m. to 1.17 p. m.—Most of the night was cloudy, but at 9.45 a. m. and at 1.17 p. m. traces of aurora were observed among the clouds.

January 25, 3 a. m. to 1,50 p. m.—Early in the evening there were indefinite streaks in the

NE., which may have been auroral, but the brilliant moonlight rendered it impossible to be sure of this. At 3 a. m. a rather broad, striated, hazy band (brightness 1) crossed the zenith from near horizon ESE, in Hydra to Vulpecula NNW., at an altitude of about 15%, passing through Cancer, Lynx, Camelopardalis, Cassiopeia, Cephens, Lacerta, and Cygnus (close to  $\varepsilon$ ). This was in the same position at 3.15, but was narrower, paler, and very sinuous and twisted. At the next two hours there were no traces of aurora, but at 6.15 there were two bands of yellowish-green streamers, starting from Boötes, one going N. through Corona Borealis, Draco, and Cygnus, and the other S. through Coma Berenices, Leo Minor, and Gemini. The streamers vibrated rapidly from W. to E. (brightness 1 to 2). At 7.15 there were faint traces in the S. At 8.15 two quiet bands (brightness 0 to 1) ran through Boötes, Canes Venatici, Ursa Major, Auriga, and Perseus. The aurora then died away to mere traces, which were wholly gone at 11 a, m., reappearing at noon, and gradually developing, first into sinuous streaks across the zenith with streamers in the SE., and then into a corona (brightness 0 to 1) centering in Ursa Minor. This was replaced by a narrow sinuous band at 1.17 running through Cygnus, Ursa Major, and Leo Minor. Traces of this band were still visible at 1.50, when the daylight was quite bright. A magnetic disturbance commenced at 3 a.m. and was still going on at 3 p. m. (10 a. m. local time), with one maximum at 6 a. m. and one at 2 p. m., both with very high eastern declination and very low horizontal force.

January 25 and 26, 1883, 10.15 p. m. to 1.17 p. m.—As soon as it grew dark enough for an aurora to be visible a faint arch appeared in the NE, with its extremities NNW, and ESE,, passing through Boötes, Canes Venatici, Ursa Major, Leo Minor, Lynx, and Gemmi. The altitude of the crown was about 50°. At 11.15 this had developed into a zone, with its extremities NW, and SE. The northern edge ran through Hercules, Draco, Ursa Major, Lynx, Gemini, and Orion, and the southern edge through Orion, Auriga, Perseus, Cassiopeia, Cepheus, Lyra, and Hercules (brightness I to 2). At 12.15 a. m. waving bands of curtains ran through Serpens, Cygnus, Lacerta, Andromeda, Taurus, and Orion, and there was also a hazy patch in Orion, Gemini, Cancer, and Leo. At 1 a. m. a broad, hazy, sinuous band, festooned and breaking into streamers and irregular patches in the NNW., ran from the ESE, in Monoceros to the NNW, in Hercules, through Canis Minor, Gemini, Lynx, Auriga, Camelopardalis, Ursa Major, Ursa Minor, and Draco. There was also a luminous patch in Taurus continued by an imperfect band through Cassiopeia, and a band in the E. from Leo through Leo Minor and Canes Venatici into Boötes (brightness 1). At 1.15 this was broken and mostly faded, except the band in the E. and streamers in the NNW. There was nothing left at 2 a. m. except a few streamers in the N. and NNW, in Lyra and Hercules, which had developed at 2.15 into four slightly diverging, sinuous bands (brightness 0 to 1), all ending in the clouds in the SE. One passed through Draco and Ursa Major, one through Draco and Ursa Minor, one fading near a Cygni, through Cepheus, Cassiopeia, and Camelopardalis, and one through Lacerta and Cassioneia. At 3 there were broken streamers in the N, and NW,, and one pale band across the western horizon through Pegasus, Aries, Taurus, and Orion. This was replaced at 3.15 by three bands, narrow and rather hazy, starting between Vulpecula and Pegasus NNW, to NW., the upper through Cygnus, Cassiopeia, Camelopardalis, Auriga, and Gemini, growing very pale; the next through Pegasus, Andromeda, Perseus, & Aurigae into Gemini, and the lowest through Pegasus, Triangulum, Aries, Taurus, and Orion, all fading in the moonlight in the SE. (brightness 0 to 1). At 4 a. m. there was a regular narrow arch (brightness 2) tinged with green and rose in the W., with an altitude of about 25°, running from the ESE, in Hydra (just below a) to the NW, just below γ Pegasi, through Monoceros, Orion (δ), the lower part of Taurus, Cetus (α), and Pisces. At 4.15 it was lower, passing through the nebula in Orion, and paler (1 to 2) with a band above it (brightness 1) through Canis Minor, Gemini ( $\gamma$ ), Taurus, and Aries ( $\alpha$ ). The needles were agitated. At 5.15 a yellowish band, waving very slowly, ran from Cygnus through Draco, Ursa Minor, Ursa Major, Leo Minor, and Leo to Hydra, while a second band commenced from Cygnus through Lyra, Corona Borealis, Canes Venatici, Boötes, and Coma Berenices to Leo (brightness 1). At 6.15 a quiet band (brightness 0 to 1) extended from Cassiopeia through Cygnus, Hercules, and Serpens to Boötes. Nothing remained at 7.15 except traces in the SW. At 8.15 a faint, quiet band ran from Taurus through Auriga, Gemini, and Leo. At 9.17 there was a small patch in the SF and a parrow, white, and quiet band running thence through Boötes, Coma Berenices, and Leo, and also a bright patch in the SW, in Gemini (brightness 1 to 2). At 10.15 a broad, irregular, white, quet

reaks in the

band (brightness 1 to 2) ran from the E. through Hercules, Corona Borcalis, and Canes Venatici to Leo Minor, with a patch of the same character in the WNW, from Orion through Auriga. At 12.15 there were faint traces of aurora in the ESE, and S. At 1 p. m. traces of streamers appeared through Aquiba, Lyra, Ursa Major, and Boötes. The last faint traces were seen at 1.17 p. m. A magnetic disturbance commenced at 5 a. m. and lasted till 5 p. m., being most violent at 5 a. m., 9 a. m., and 3 p. m.

January 26 and 27, 10.15 p. m. to 12.15 p. m.—At 10.15 p. m. there was a faint and narrow arch in the NE, through Canis Minor, Cancer, Leo Minor, Coma Berenices Canes Venatici, and Boötes. At 11.15 this was broken up into a hazy mass in Canis Minor, Cancer, and Leo, and streamers in Serpens and Boötes, and at 12.15 was reduced to a faint flush in the NE. At 1 a.m. there were two bands of short, ill-defined streamers in the NE., the upper from Hercules in the NNW, through Corona Borcalis, Boötes, and Canes Venatici, and the lower through Leo ( $\rho$  and  $\delta$ ) and Coma Berenices, starting in Hydra and ending near a Beotes (brightness 0 to 1). These bands were essentially unchanged at 1.15, but a bunch of streamers had developed at the NNW, end reaching up into Draco. At 2 a. m. nothing remained but traces of the bands. These traces were better defined at 2.15, and there was a twisted streak (brightness 1) from close to a Vulpeculae (NNW.) through Cygnus ( $\beta$  and  $\delta$ ). At 3 a narrow arched and somewhat sinuous band (brightness 1) extended from NNW, in Vulpecula to ESE, in Hydra, through Cygnus ( $\beta$ )  $\alpha$  Lyra, Draco, the top of Boötes, Canes Venatici ( $\alpha$ ), and Leo ( $\delta$  and  $\theta$ ). At 3.15 this band was paler and formed an outlying band of a zone with the same starting points. The western edge of the zone ran through Leo, Gemini, Auriga, Perseus, Andromeda, and Pegasus, and the eastern through Leo, Leo Minor, Ursa Major, Camelopardalis, Ursa Minor, Cepheus, and Cygnus, while there was an arched band low in the E. from  $\beta$  Leonis to  $\alpha$  Boötes. At 4 a.m. there was a hazy zone (brightness 0 to 1) with its starting points in the ESE, in Crater and NW, below , Pegasi. The western edge ran through Leo, Leo Minor, Lynx, Camelopardalis, Cassiopeia, and Andromeda, and the eastern through Leo, Cancer, Gemini, the top of Orion, Taurus (a), and Aries. At 4.15 the zone was in nearly the same place, but its eastern edge had moved four or five degrees W., while a twisted streak (brightness 2 to 3), very sinuous and tinged with green and rose, began to move up from the ESE., spreading out and beginning to wave, at first slowly and then rapidly, as it approached the zenith, passing up through Ursa Major and Cassiopeia (where it stopped) in 2 or 3 minutes, while the zone faded. It was brightest near the horizon. At 4.17 and 4.18 a second similar band was beginning to develop a little to the E. of this. At 5.15 a belt of quiet bands ran from Pegasus through Lacerta. Cygnus, Cepheus, Draco, Ursa Major, and Coma Berenices, while the lower edge passed through Cygnus, Lyra, Sagitta, Hercules, Corona Borealis, Serpens, and Boötes (brightness 1 to 2). Only traces remained at 6.15. At 7.15 there were two bands (brightness 0 to 1), one through Taurus, Perseus, Cassiopeia, Cepheus, Cygnus, and Corona Borealis, and the other through Cepheus, Draco, Ursa Major, and Coma Berenices. At 8.15 a quiet band (brightness 0 to 1) ran through Vulpecula, Hercules, Serpens, and Boötes. At 2.15 this was reduced to a streak, lying only in Hercules and Corona Borealis, with faint traces in the NW. At 10.15 a broad irregular mass of rays, converging towards the zenith (brightness 4), occupied Cassiopeia, Cepheus, Ursa Minor, Camelopardulis, Ursa Major, Draco, Canes V. atici, Coma Berenices, Boötes, and Serpens. This body of rays was slightly tinged with green and rose, and vibrated easterly, having also a slow but constant change of form and position. The western sky was filled with long, fine streamers from Canis Minor to Aries, and there was also a diffuse, white, quiet arch from the SE, to the NW., with its crown at an altitude of about 10° above the southern horizon (brightness 0 to 1). At 11.15 there v is a broad striated band (brightness C to I) running ESE, and WNW, through Hercules, Cerona Borealis, Ursa Major, Ursa Minor, Lynx, Aquila, and Gemini, white and quiet. At 12.15 there were very faint traces of an arch running ESE, by WNW., passing a little south of the zenith. A magnetic disturbance commenced at 4 a. m. and continued about ten hours, being at no time very large, but reaching its maximum a, 11 a, m.

January 27 and 28, 10,15 p. m. to 12.15 p. m.—The aurora began at 10,15 as a faint streak in the NE, which by 11 o'clock had developed into an arch of streamers through Canis Minor, Cancer, Leo, Coma Berenices, and Boötes (brightness 2), faintly tinged with green and rose, and in rapid vibration from E. to W.—This had become quiet and faded to brightness 1 at 11,15.—At

g at no time

12.15 there were two parallel bands of curtains from the NW. to ESE., through Cancer, Leo, Leo Minor, Canes Venatici, Ursa Major, Bcötes, Corona Borealis, and Hercules, moving but slightly (brightness 1 to 2). At 1 a. m. nearly the whole eastern sky was covered with aurora (brightness 2). A broad sinuous band ran from near a Hydra in the ESE, to Cygnus in the NNW., through Leo, Leo Minor, Canes Venatici, Ursa Major, Draco, Hercules, and Lyra, while above this were three series of broad indistinct curtains radiating from the zenith and not reaching west of Gemini and Cassiopeia. At 1.15 the curtains were fading, leaving the bands which were slightly tinged with green and rose in the ESE. At 2 a, m, there was a broad, somewhat sinuous band (brightness 2) in the NE., from the NNW, in Hercules to the ESE in Hydra, through Corona Borealis, Canes Venatici, Ursa Major, and Leo  $(\beta$  and  $\theta)$ , with traces of a streak through Cassiopeia and Gemini. At 2.15 there were also partial coronal streamers (brightness 1) occupying Leo, Leo Minor, Ursa Major, Ursa Minor, Draco, Cepheus, Cygnus, and Cassiopeia, centering towards Polaris, with pale bands branching off from the ESE, in Gemini. At 3 and 3.15 there was a narrow, rather regular arch (brightness 1 to 2) in the NE, from the ESE,, low in Leo to the NNW. in Hercules, through Virgo, Coma Berenices, a Boötis, Corona Borealis, and Serpens, with a streak (brightness 0 to 1) E. by S. from Leo up into Gemini. There were only faint traces at 4, but at 4.15 these had developed into two bands (brightness 0 to 1) starting, respectively, NNW, and NW., one through Cygnus and the other through Pegasus, Andromeda, and Cassiopeia, faintly visible as far as Leo. At 5.15 a quiet band (brightness 1) ran from Hydra through Canis Minor, Orion, and Taurus to Cetus. Faint traces were observed at 6.15 and 7.15 a. m. No more was seen till 11.15 when a broad, diffuse, quiet arch (brightness 0 to 1) ran from the ESE, to the WNW., through Corona Borealis, Ursa Major, and Gemini. The last faint traces were seen in the ESL, at 12.15 p. m. The horizontal force was unusually high from about an hour before the beginning of the aurora, but returned to its ordinary reading at about 3 a.m., remaining undisturbed till 1 p. m., when there was a slight disturbance for a couple of hours, the horizontal force falling and the declination rising. The vertical intensity was rather high all day.

January 28 and 29, 1883, 10.15 p. m. to 12.35 p. m.—There was a faint streak in the NE. at 10,15 p, m., and faint traces were again visible in the ENE, at 11.10 and in the NW, again at 12 midnight. There were traces in the N. and E. at 1 a. m., which had developed at 1.15 into a slightly sinuous arched band (brightness 1) from the NNW, in Hercules to the ESE, in Hydra, through Corona Borealis (a), Boötes (z), Coma Berenices, and Leo (3). At 2 a.m. the arch was in the same position, but had faded to brightness 0 to 1, and there was a second similar arch a little above it, passing through Canes Venatici and \(\beta\) Boötis. This had faded to traces at 2.15. At 3 there were two bands (brightness 0 to 1), beginning in nearly the same place in Hydra, but fading in Coma Berenices, with a trace also in the N. This developed at 3.15 into a somewhat sinuous band (brightness 1) from ESE, in Hydra to the NNW, in Vulpecula, through Leo  $(\theta)$ , Coma Berenices, Canes Venatici (a), Boötes, Draco ( $\beta$  and  $\gamma$ ), and Cygnus close to  $\delta$ . At 4 a. m. a festooned band (brightness 1 to 2) started from nearly the same point in the NNW., and passed through Cygnus, Draco. Boötes, Canes Venatici, Coma Berenices, and Leo, the ESE. in Virgo. This had become straighter at 4.15 and from the ESE, end came curved radiating streamers through Leo, Leo Minor, and Ursa Major, all slowly shifting. At 5.15 there were only traces in the NE., and no more was seen till 7.15, when there was a quiet, yellowish band (brightness 1) from Aries through Andromeda, Cassiopeia, Lacerta, Cygnus, and Lyra to Hercules. A fainter band (brightness 0 to 1) at 8.18 ran from Taurus through Orion, Gemini, Cancer, and Leo to Virgo. At 9.15 a broad, pale, quiet arch extended from the ESE, to WNW, with its crown at an altitude of about 18-, and above it a second similar arch from the same starting points, through Corona Borcalis, Ursa Major, and Gemini. There was also an irregular arch of quiet streamers from the E. to NW, through Cygnus, Lacerta, Andromeda, Perseus, and the Pleiades. At 10.15 there was a broad, quiet arch (brightness 0 to 1) from the ESE, to the WNW., with its crown at an altitude ef 20°, with a similar arch from Hercules through Corona Borealis, Canes Venatici, Leo Minor, Cancer, and Canis Minor. No more was observed till 12.15 p. m., when there was a broad, quiet white band (brightness 0 to 1) from the ESE, to the WNW, through the zenith, and from Polaris to the lower extremity of Ursa Major. The needles were unusually quiet all night though there was a slight disturbance at 9 a.m.

January 29 and 30, 1883, 11.15 p. m. to 1 p. m.—There was a faint streak along the horizon in the NE, at 11.15 which developed into an ill-defined arch of pale streamers, and had subsided to a faint glow at 12.15 a.m. At 1 and 2 faint traces only were visible, and absolutely no aurora was visible at 3. At 4, however, there was a well marked, rather narrow zone (brightness 1), with its starting points ESE, in Leo and NNW, in Pegasus, occupying part of Leo (ξ, δ, and θ), Coma Berenices, and Canes Venatici, Ursa Major, Ursa Minor, Cephens, Draco, Lacerta, the top of Cygaus (not inclosing a), and Andromeda, with an outlying band through Cassiopeia. At 4.15 the starting points were nearly the same, but the aurora had drifted westward so as to occupy Pegasus, Andromeda, Perseus, Cassiopeia, Auriga, Camelopardalis, Lynx, Leo Minor, and Leo, where it was brighter (1 to 2) and much convoluted. This was essentially unchanged at 5.15. At 6.15 a quiet band (brightness 1 to 2) ran from Pegasus through Cygnus, Lyra, Hercules, Corona Borealis, and Boötes to Coma Berenices. At 7.15 a quiet band (brightness 1) ran from Cancer through Gemini, Auriga, Taurus, and Pisces. At 8.15 there were merely traces near the horizon in the N.  $A_1$ 9.10 bands (brightness 1) ran through Cassiopeia, Perseus, Cygnus, and a Lyrae. At 10.10 a band (brightness 2) ran through Ursa Minor, Ursa Major, Auriga, Boötes, Coma Berenices, Leo Minor, Gemini, Cepheus, Hercules, and Corona Borealis. At 11.15 a bright band (brightness 4) ran through Ursa Major, Boötes, Gemini, Auriga, Cassiopeia, Cygnus, Draco, and Lyra. At 12.40 p. m. there were traces in the NW, and N, at an altitude of 20° and 56°, and the last faint traces were seen in Lyra and in the S, at 1 p. m. The magnetic needles were unusually quiet all night.

January 31, 1883, 1 a. m. to 10.10 a. m.—Faint glimmers of aurora were observed in the NE. early in the evening, but there was no definite aurora till 1 a.m., when there were two broad bands of somewhat indefinite curtains (brightness 1) across the eastern sky, with slight waving motion running from Leo in the ESE, to Vulpecula (a) in the NNW., through Leo, Lynx, Ursa Major, Ursa Minor, Draco, Lyra, and Cygnus. These had changed at 1.15 into a broad band from the same starting points, running through Cancer, Gemini, Auriga, Camelopardalis, Cepheus, and Cygnus (brightness 1 to 2). It was brightest (brightness 2) in the NNW., and towards the ESE, was split longitudinally in two, and very sinuous near the Lorizon. At 2 a. m. a broad band (bright ness 2 to 3), somewhat inclined to split lengthwise, and sinuous near the horizon, swept waying slightly from the NW, to the E. by S., occupying Pegasus, Andromeda, Lacerta, Cygnus, Cepheus, Draco, Lyra, Ursa Major, Leo Minor, and Leo. At 2.15 a broad band swept round from NW, to ENE., about 35° above the horizon, from Pegasus, through Andromeda, Perseus, Auriga, Gemini, Leo, Leo Minor, Ursa Major and Canes Venatici into Draco: there joining three spiral bands, making a sort of vortex between Draco and the zenith (brightness 2 to 3). The magnets were somewhat disturbed, especially the declination magnet, the eastern declination increasing about 19. At 3 a. m. the SE, sky from near \( \alpha \) Hydrae to near \( \alpha \) Boötis was filled with exceedingly sinnous broad bands (brightness 1 to 2), reaching nearly to the zenith, the most southern being continued in the form of a narrow zone through Cancer, Gemini, Taurus, Aries, Triangulum, and Pegasus, ending in the NW. At 3.15 the bands were less sinuous and longer and the zone marower and brighter (2 to 3). At 4 there was a very broad zone across the zenith (brightness 1 to 2). The starting points were between ESE, and E, by S, in Crater and Hydra, and NW, in Pegasus, The western edge ran through Virgo, Boötes (a), Corona Borealis, Lyra, and Cygnus, and the western through Hydra, Canis Minor, Orion, Taurus, Aries, and Pegasus. At 4.15 the zone was fading and breaking up, except the eastern edge, which had narrowed into a band (brightness 3faintly tinged with rose on the lower edge, above which in the NE, was "eveloping a row of imperfeet curtains. At 5.15 four quiet yellowish bands started from Pegasus NW, (brightness 4 to 2). running as follows: The first, north of the zenith, through Lacerta, Cygnus, Draco, and Canes Venatici, ending in Virgo: the second, through Cassiopeia, Cepheus, Ursa Minor, Ursa Major to Virgo; the third, south of the zenith through Andromeda, Persons, Auriga, and Lynx to Leo; and the fourth, through Aries, Taurus, Orion, and Canis Minor to Hydra. At 6.15 there was a zone running W. and E. (brightness 2 to 3), with the northern edge waving slowly. The starting points were in Aries and Boötes. The southern edge ran through Taurus, Gemini, Leo, and Coma Berenices, and the northern through Pisces, Andromeda, Cygnus, Lyra, and Corona Borealis. At 7.15 the zone had essentially the same position and form, but had faded (brightness 0 to 1). Faint

traces continued to be visible at 8.15, 9.10, and 10.10, after which the weather became hazy. There was a magnetic disturbance at 5 to 6 a. m., greatest at 6 a. m.

February 1, 1883, 5.15 a.m. to 1.15 p.m.—Traces of small luminous patches appeared in the west at 5.15 a.m. At 6.15 a, m, one white and quiet band (brightness 2) ran from SE, to WYW, along the horizon, while there was an arch of short streamers of the same color and brightness, somewhat irregular, from the same starting points, about 16° higher than the first band, passing through Leo, Cancer, Gemini, Otion, and Taurus. At 7.15 there was a large corona (brightness 2 to 3), centering in Ursa Major south of the zenith; and a bright band of streamers, vibrating rapidly from W. to E., ran through Pegasus, Aries, Taurus, Auriga, Gemini, and Leo Minor. At 8.15 there was a broad arch from ESE, to WNW., with the crown about 15° from the southern horizon, with a second sim-Har arch above it, from the same starting points through Boötes, Canes Venatici, Ursa Major, Lynx, Gemini, and Orion. From the western extremity came a third similar arch through Taurus, Camelopardalis, Ursa Minor, Draco, and Hercules, ending near the eastern horizon. At the same time a broad irregular broken band of short streamers, quivering slightly, extended from the ENE. through Lyra, Cygnus, Lacerta, Andromeda, Triangulum, Aries, and the Pleiades (brightness of all, 2). At 9.15 there were traces only in the S. At 10.15 there was a broad and quiet white arch from the ESE, to WNW,, with its crown about 45 above the southern horizon, and long white motionless streamers in the E. and ENE., in Hercules, Sagitta, Cygnus, Lyra, and Draco. At 11.15 there was a broad waving band from E. to W. through Gemini, Ursa Major, Draco, Lyra, and Cygnus (brightness 1), and a long low arch in the S.; 12.15 p. m. there was a broad quiet band from the E. to W. from Leo through Coma Bereniees, Boötis, and Aquila, with a corona in Ursa Major. At 1.15 a corona, with its streamers thickest in the E, and W,, was barely discernible in the bright twilight. The needles were comparatively quiet up to nearly half past 12 p. m., when a violent disturbance began, which is still going on.

February 2, 1883, 1 a. m. to 12.15 p. m.—Early in the evening the haze and clouds were thick, but at 1 a. m. (8 p. m. local) traces of twisted bands, apparently bright and in motion, were visible through the clouds, crossing the zenith from NW, to SE. These were very faint at 1.15. The clouds were thicker at 2 a. m., and the traces consequently fainter. None were seen at 3 a. m. At 4 the haze grew thinner, allowing the central part of a broad zone to be visible. The starting points were invisible in the haze in NW, and SE,, and the whole was much obscured by haze. In breadth it reached from Ursa Major to Taurus. The sky was much clearer for four or five hours, gradually becoming obscure again. At 5.15 an aurora was observed passing through Canis Minor, Orion, Taurus, and Cetus (brightness 0 to 1). At 6.15 there were two faint bands, one from Cancer through Orion, Taurus, and Aries, and the other through Gemini, Auriga, Perseus, and Andromeda (brightness 0 to 1). At 7.15 a short band crossed the zenith from Hercules through Ursa Major, Camelopardalis, and Gemini. Farther south of the zenith yellowish white bands ran from Ursa Major to Canes Venatici, Coma Berenices, and Leo Minor, and there was a band of streamers, in rapid waving motion, passing through Serpens, Boötes, Coma Berenices. Leo, Cancer, and Gemini (brightness 1 to 2). At 8.15 there were only faint traces along the horizon. At 9.15 a broad, white, quiet, irregular arch from the SW, horizon through Cancer, Leo Minor, Ursa Major, Canes Venatici, Corona Borealis, and Hercules, ending in Serpens. At 10.15 the haze and clouds were again becoming thicker, and traces of an arch were observed running from ESE, to W. about 10° south of the zenith. At 11.15 a broad zone (brightness 0 to 1) covered most of the southern sky, the bands running from ESE, to W. The first ran through Sagitta, Lyra, Draco, Ursa Major, and Leo Minor, and the second through Hercules, Corona Borealis, Coma Berenices, and Leo, while a broad irregular patch ran from the SSE, to SW, through Serpens, Boötes, and Leo, with a smaller luminous streak near the horizon in Virgo. The last faint traces were seen at 12.15 p. m. A magnetic disturbance began at 4 a, m, and continued all night.

February 3, 1883, 1 a. m. to 11.15 a. m.—The sky was cloudy early in the evening, but the clouds broke sufficiently at 1 a. m. (about 8 p. m. local) to show a regular, narrow arch in the SW. (brightness 2), from the SE. to NW., with its corona at an altitude of about 40°, partially obscured by clouds. The arch was partially broken and irregular at 1.15. At 2 the haze was thick again, but through it near the zenith in the SE, there were traces of an extensive and apparently bright aurora which was nearly obscured at 2.15. There was less haze again at 3 and a broad band consid-

e horizon in subsided to o aurora was ss 1), with its , Coma Berep of Cygnus .15 the start. npy Pegasus. where it was t 6.15 a quiet Borealis, and ough Gemini. the N. ness 1 to 2), b, and Canes rsa Major to yux to Leo; there was a The starting o, and Coma orealis. At

o 1). Faint

erably obscured from the SE, to NW, through Polaris could be seen. At 4 there were traces near the zenith, but at 4.15 the haze was nearly gone, displaying extensive bands forming a sort of vortex. One broad band (brightness 2) began in the top of Cygnus, in the NNE., as an irregular cloudy patch, and passed round through Lyra, Hercules, Boötes, Canes Venc'ici, Ursa Major; Lynx and Auriga, ending in Perseus, whence just below the edge of this a double band (brightness 1) ran back to Gemini. There was also a broad band (brightness 2) somewhat obscured by clouds on the SW, horizon through Orion. At 5.15 one band of streamers passed through Lyra, Hercules, Corona Borealis, Boötes, and Coma Berenices, and another from Pegasus through Aries, Taurus, Orion, and Gemini to Cancer, but vibrating slowly from E. to W. (brightness 2). At 6.15 a quiet band (brightness 0 to 1) ran from Pegasus through Cygnus, Vulpecula, and Serpens. At 7.15 a quiet yellowish zone (brightness 1 to 2) filled the southern half of the sky, and one outlying band from Ursa Major to Cygnus in rapid, waving motion. At 8.15 there were seen traces of a corona covering the whole sky from the horizon, centering a little south of the zenith. At 9.15 there were four broad bands (brightness 1) covering most of the sky, the first in the north from NW, to NE., with the crown at an altitude of about 12°, the second from E. to W. through Polaris, the other two starting together from the ESE,, the west one passing through Hercules and Ursa Major, and the other through Corona Borealis, Canes Venatici, and Leo Minor, with also a broad band of luminous patches from the ESE, to W. about 15° above the southern horizon. At 10.15 there was a zone of three bands (brightness 0 to 1), with its starting points ESE, and NNW., one through Lyra, Draco, Ursa Major, Lynx, Gemini, and Canis Minor, the second through Corona Borealis, Canes Venatici, and Leo Minor, and the third through Serpeus, Boötes, Coma Berenices, and Leo. At 11.15 there was a white, quiet arch from the NW, to E. through Auriga, Cassiopeia, and Lacerta (brightness 0 to 1), with streamers at the extremities, and also short curved streaks in the south in Boötes, Hercules, and Coma Berenices, and a broad broken band from the SE, to SW, about 10° above the southern horizon, all of the same brightness. The weather then became too thick for further observation. A violent disturbance, affecting all the magnetic elements, commenced about 2 a. m. and lasted about twelve or thirteen hours, being specially violent at 2 and 8 a. m. and 1 p. m.

February 4, 1883, 12.15 a. m. to 11.15 a. m.—The early part of the evening was very stormy, the wind reaching 54 miles an hour, with the drifting snow rendering accurate observation of the aurora impossible, though the sky frequently was almost clear of clouds. Hazy light was observed in the NE, at 12.15 a.m., and bright traces in the NE, at 1 a.m. At 2 a.m. there was a broad zone across the zenith from the NW, to SW, (brightness apparently 1). At the next two observations the sky was completely covered with clouds, and traces only were seen near the zenith at 3 a. m. and in the SE, at 4. At 5 the sky was clearer, showing a band (brightness 0 to 1) from Cancer through Canis Minor, Orion, and Taurus. At 6 a brighter band (brightness 1) ran from Leo, through Gemini, Auriga, and Taurus to Aries. At 7 there were two yellowish bands (brightness 1 to 2), the first from Leo, through Lynx, Camelopardalis and Cassiopeia, to Andromeda, and the second from Cygnus, through Draco to Ursa Major. At 8 there were merely traces round the southern horizon and a few patches in the W. At 9.15 there was a broad white band on the southern horizon, with streamers in Serpens and Boötes. There was besides a white arch from the SE, to NW, through Corona Borealis, Draco, Ursa Major, Auriga, and Orion, and a similar band from E. to N. through Sagitta, Vulpecula, Lacerta, and Andromeda, and streamers in Pleiades (brightness 1). At 10.15 a band ran along the northern horizon from the NW, to ENE., and a striated band from the SE, to NW, through Hercules, Draco, Ursa Major, Lynx, Cancer, Gemini, and Canis Minor. There was also a broad band near the southern horizon from SE, to SW. There were also streamers in the E. All were white and quiet (brightness 0 to 1). This was essentially unchanged at 11.15, after which the sky again became overcust. A violent disturbance began at 3 a. m. and lasted all night.

February 4, 1983, 10.45 p. m. to 11.15 p. m.—The sky, which had become overcast all the after noon, became sufficiently clear at 10.45 p. m. (about half-past 4 local) to show an arch in the NE., with its extremities bearing ESE, and NNW., and its crown at an altitude of about 45°. The sky then became again overcast with snow, but auroral light was still visible at 11.15 p. m. through

traces near ig a sort of ın irregular 'rsa Major; uid (brightbscured by rough Lyra, us through ightness 2), la, and Serhe sky, and e were seen the zenith. n the north W. through th Hercules Minor, with ern horizon. s ESE, and ond through oötes, Coma ngh Auriga,

February 6, 1883, 12.15 a. m. to 12.15 p. m.—The early part of the evening was cloudy and stormy. However, at 12.15 a.m. traces were visible through the clouds in the NE. At 1 a.m. the clouds were broken away somewhat, and much bright light, obscured by broken clouds, was visible in the E. For the next six observations the clouds were thick and the weather stormy. At 8.15 a yellowish-green band, with short, motionless streamers (brightness 1 to 2), ran from Orion and Taurus, through Auriga, Perseus, Cassiopeia, Andromeda, Cygnus and Draco. At 9.15 there was an aurora of essentially the same character as at 8.15. At 10 an arch of diffused light (brightness 1 to 2) ran from the ESE, to WNW,, with its crown at an altitude of about 15° above the southern horizon. At the same time a band of similar character ran from the E. to NW., through Cygnus, Ursa Minor, and Auriga. The latter had disappeared at 10.15, the former remaining unchanged. At 11.15 there was a broad band of quiet streamers, with its grown at an altitude of about 150 above the southern horizon, running from ESE, to WNW., and an elliptical corona continuing towards the zenith with its greatest diameter E. and W., the rays changing position rapidly at short intervals (brightness 2). There was still a corona of the same form at 12.15, but paler (0 to 1) and quiet, brightest in the W., and fading in the E., occupying Cancer, Lynx and Camelopardalis in the N. and Leo Minor, Canes Venatici and Hercules in the S. It was broad daylight at the next observation. A magnetic disturbance of considerable violence began about 5 a.m. and continued all night (local), reaching its maximum about 12 m. (Washington time).

February 7, 1883, 12.15 a. m. to 1 a. m.—The sky was hazy during the early part of the evening, but a faint arch was discernable at 12.15 a. m. in the NE. from ESE, to NNW., with its crown at an altitude of about 30°. There were also traces at 1 a. m., but after this the sky became overcast and the weather cloudy and no more aurora was seen. The magnetic needles were but little dis-

turbed, although the intensity was very small.

February 8, 1883, 3 a, m. to 10,15 a, m.—Traces of a low arch were observed in the NE. at 3 a. m., somewhat obscured by haze, and at 3.15 this arch had risen so as to pass from WNW, to ESE. through Cygnus, Lyra (a), Corona Borealis, Bootes and Coma Berenices. At 4 a, m, a zone, not very broad and rather hazy (brightness 1), had its starting points ESE, and NW, in Virgo and Pegasus, with its western edge running through Leo, Minor, Ursa Major, Camelopardalis, Cassiopeia and Andromeda, and its western through Leo Cancer Gemini, Taurus, Aries and Triangulum. This was somewhat narrower and less hazy at 4.15. At 5.15 a broad, yellowish, quiet band (brightness 1) ran from NW, in Pegasus to ESE, in Coma Berenices and Boötes, the eastern edge through Cygnus, Lyra, Draco, Canes Venatici and Boötes, the western through Lacerta, Cassiopeia, Ursa Minor, and Ursa Major. At 6.15 the main band, waving slightly, ran through Pegasus, Andromeda, Cassiopeia, Camelopardalis, Ursa Major, Coma Berenices and Boötes, with a small secondary band from Lacerta through Cygnus, Draco, and Boötes (brightness of all, 1 to 2). At 7.15 there was only a faint band (brightness 0 to 1) through Virgo, Leo, Cancer, Gemini and Taurus, and at 8.15 merely traces around the southern horizon. At 9 a.m. a belt of streamers (brightness 2), about 200 long, white, and quiet, encircled the entire horizon, and at an average altitude of about 10°. At 9.15 there was an arch from the SE, to SW, with its crown at an altitude of about  $40^\circ$  above the southern horizon, and a broad striated band starting from the same point in the SE, and running to the NW., including Ursa Major in the S. and Cassiopeia in the N., with an arch of short rays, centering towards the zenith, starting from the NW, end of the band and running through the Pleiades, Aries, Andromeda, Cygnus and Sagitta. All were white and quiet (brightness 2). At 10.15 there was a white, quiet, diffused arch from the ESE, to WNW., with its crown at an altitude of about 150 above the southern horizon, with an arch of streamers from E. to NNW., through Cygnus, Ursa Minor, Camelopardalis and Taurus, slowly changing in form (brightness 2). The arch was in the same place at 11.15, but paler (brightness 0 to 1) and there were a few faint streamers in the E. and NW. The magnetic intensity still continued low, and there was a slight disturbance, lasting from 8 a. m. to about 1 p. m.

February 10, 1883, 8 a. m. to 11.15 a. m.—The violent storm having moderated about 8 a. m. (3 p. m. local), a quiet band was visible through the haze, passing through Leo, Cancer, Gemini and Taurus (brightness 0 to 1). At 9.15 traces were visible in the SW., and at 10.15 there were

H. Ex. 41---51

observed through the base a few traces of auroral streamers, white and quiet. At 11.15 there was a definite band, white and quiet (brightness 1), running about E. and W. through Lyra, Draco and Ursa Major. Daylight began before the next observation. The magnetic needles were considerably agitated during the whole night, making large oscillations, but there was no regular disturbance.

February 11, 1883, La, m, to 11.15 a, m,—At about 8 p, m, local time (1 to 1.15 a, m., Washing ton) there were faint traces in the E. in the form of a low, pale arch. At 2 a. m. there was a pale. vertical streak in the ESE, which developed at 2.15 into an irregular band (brightness 0 to 1) sinuous in the ESE, from ESE, in Leo to the NNW, in Cygnus, through Leo (β), Coma Berenices, Canes Venatici (α), Boötes (λ), Hercules and Lyra. This band was hardly changed at 3 a. m., having merely moved a trifle higher so as to pass through the tail of Ursa Major, and at 3.15 it was fading, leaving merely the part south of the magnetic meridian. At 4 a.m. a rather broad, sinuous band (brightness I) crossed the zenith from the ESE, in Virgo to the NW, in Andromeda, through Leo, Coma Berenices, Ursa Major, Camelopardalis, Ursa Minor and Cassiopeia. At 4.15 this had become a narrow zone, broadest in the ESE., with the same starting points, but passing west of the zenith through Draco and Cepheus, waving slowly near the zenith and drifting westward. This developed into a very broad and bright zone between the observations, diminishing to a band at 5.15, and passing through Pegasus, Andromeda, Perseus, Auriga, Ursa Major and two Minor (brightness 1). At 6.15 a similar band ran through Pegasus, Lacerta, Cygnus, Praco, Corona Borealis and Boötes. At 7.15 a paler band (brightness 0 to 1) passed through Aries, Taurus, Orion, Gemini, Cancer and Leo, but at 8.15 there were merely traces over the southern horizon. At 9.15 there was a quiet white arch (brightness 1) from the SE, to NW., with its crown at an altitude of about 15° from the southern horizon, with streamers at the SE, end of the arch in Corona Borealis and in the NE, in Cygnus, Vulpecula and Lacerta. The arch had risen a little at 10.15, and reached to the NNW. At the same time the entire southern half of the sky was filled with a diffuse light (brightness 0 to 1) and pale streamers (brightness 0 to 1) forming a corona and occupying Taurus, Gemini, Camelopardalis, Perseus, Cassiopeia, Cepheus, Lacerta and Cygnus. At 11.15 the greater portion of the sky between the zenith and the southern horizon was filled with nearly parallel bands (brightness 0 to 1) running ESE, and WNW, from horizon to horizon. There was a slight magnetic disturbance from 10 to 11 a. m.

February 13, 1883, 9.15 a, m, to 10.15 a, m.—Though the early part of the evening was clear, it became cloudy by 2 a, m., local time, but the sky was partially clear at 9.15 and 10.15 (Washington). At the first observation faint traces, with slight motion, slowly shifting, were visible near the zenith and in the NW., and at the latter faint traces could be seen through the haze and clouds. The needles were but slightly disturbed.

February 14, 1883, 4.15 a. m. to 8.15 a. m.—It was cloudy and snowing up to about 11 p. m., local time (Washington, 4 to 4.15 a. m.), when it began to clear, remaining clear till 9 a. m. (Washton). At 4 to 4.15, while the stars were still mostly obscured, a zone, apparently very broad and rather bright, was seen crossing the zenith through the clouds and haze. At 5.15 a band with motionless streamers (brightness 0 to 1) ran through Pegasus, Cygnus, Cepheus, Draco, and Ursa Major. At 6.15 there was a short band (brightness 0 to 1) through Leo and Cancer and a few patches of light in Gemini, Auriga, and Pisces. At 7.15 and 8.15 a. m. there were merely faint traces in the S. There was a moderate magnetic disturbance at 9 and 10 a. m.

February 15, 1883, 8.15 a. m. to 10.15 a. m.—Most of the night was cloudy, but it was clear from 8 till daylight. Faint traces of aurora were seen at the zenith and in the NE. at 8.15 a. m., and at 10.15 a. m. there was a white and quiet arch (brightness 1), with rays centering towards the zenith, occupying Hercules, Ursa Minor, and Gemini. It was broad daylight at the next observation. There was no magnetic disturbance.

February 16, 1883, 2 a. m. to 11.15 a. m.—At 2 a. m. there was a pale arch in the E., starting low in Leo in the ESE., passing through β Leonis, Coma Berenices, the corner of Canes Venatici, Boötes (β), and Hercules, fading near a Lyrae, with a lower branch from the same starting point reaching a Boötes (brightness 0 to 1). This had become slightly irregular and not so high at 2.15, and remained in nearly the same place, but was faded to traces at 3 to 3.15. The sky was clouded at 4 a. m. with patches of fleecy cloud, which cleared away at 4.15, partly exposing a broad broker.

5 there was Lyra, Draco es were conno regular

E., starting is Venatici, ating point igh at 2.15, ras clouded oad broker. zone of many bands (brightness 0 to 1) apparently covering most of the sky. The sky was again partially cloudy at the next observation, and traces only were visible. At 6.15 one band with streamers in rapid vibration from W. to E. passed through Boötes, Canes Venatici, Ursa Major, Lynx, and Draco, while a second band, wholly of streamers in rapid motion, ran from Leo to Gengini, with a few patches in Virgo and Boötes (brightness 1 to 2). At 7.15 a quiet band (brightness 1) crossed the zenith from Hercules through Draco, Ursa Minor, Camelopardalis, Auriga, and Taurus. There were nothing but traces at 8.15, nor was any observed for two observations, though the sky was clear, but at the next two observations traces were observed near the zenith at 10.15 and in the SW, at 11.15. At the next hour it was daylight. There was a slight magnetic disturbance at 10 a, m.

February 17, 1883, 3 a. m. to 5 a. m.—The weather was cloudy till 9 a. m., local (3 a. m. Washington), when the clouds cleared away, leaving the sky covered with haze, through which a somewhat sinuous band was visible (brightness apparently 1), crossing the zenith from near the horizon NNW, and ESE. This had broadened into a zone at 3.15 with one bright streak (brightness 1 to 2) in the NW. Most of the stars were obscured. At 4 the sky was much clearer, and there was an arched band (brightness 1 to 2) from the NNW, in Pegasus to E. by S. in Virgo, through Cygnus (ε), Lyra (just below α), Hercules, Serpens, and Boötes. At 4.15 it was paler (brightness 1), and growing double from the eastern end. It began to cloud again at 5, so that traces only were visible. There was a considerable magnetic disturbance between 8 a. m. and 1 p. m., reaching its maximum at 11 to 12.

February 18, 1853, 11.15 a. m. to ——?.—The weather was cloudy all night, but traces of aurora were visible through the clouds at 11.15 a. m.—The magnetic needles were very quiet.

February 20, 1883, 8 a. m. to 9.15 a. m.—The weather was cloudy most of the night, but cleared away sufficiently at 8 to 8.15 and 9 to 9.15 a. m. (3 and 4 a. m. local) to allow anrora to be seen. This consisted of traces merely at the first observation, but at the second of two quiet bands (brightness 0 to 1), one from Auriga through Perseus to Cassiopeia, and the other from Andromeda through Pegasus to Delphinus. The magnetic needles were considerably disturbed from 4 to 11 a. m., the disturbance reaching its maximum at 7.

February 21 and 22, 1883, 11.45 p. m. to 11.15 a. m.—The twilight had not completely faded at 7.30 p. m. (11.45, Washington), when a twisted streak tinged with yellow was observed crossing the zenith from NW, to SE. (brightness 0 to 1). By 12.15 a.m. this was reduced to a bunch of streamers in Cygnus and Lyra, and a faint band through Lyra, Hercules, and Ursa Major, and had wholly disappeared at 1 a.m. At 1.15 shifting, twisted streaks and bands of streamers with considerable motion (brightness 0 to 1), tinged with yellow and rose, appeared in the N., occupying Lyra, Cygnus, Cepheus, and Draco. At 2 a. m. a very pale band ran from Cygnus (a) in NNW, through Draco and Ursa Major (α), ending in the moonlight ESE., and was wholly gone at 2.15. At 3 a.m. there was a pale band west of the zenith, from the NW., in Pegasus, through Andromeda, Cassiopeia, Auriga, and Gemini. This was replaced at 3.15 by a similar band in nearly the same position as the one observed at 2 a. m. Traces merely were observed at 4 to 4.15. At 5 two bands ran from Boötes and Virgo through Coma Berenices, Leo, Leo Minor, Gemini, and Auriga to Taurus, with bunches of slowly vibrating streamers in Boötes and Virgo (brightness 0 to 1). Traces only were observed at 6 and 8. At 9.15 there was a quiet arch (brightness 0 to 1) in the S. from ESE, to WNW., with an altitude of about 15°, and a quiet, striated arch (brightness 0 to 1) through Hercules, Draco, and Gemini. At 10.17 a. m. the arch in the S. was unchanged, while a second similar arch about 10° to 15° in breadth ran from ESE, to SW., while a third arch ran from ENE, through Cygnus, Ursa Minor, and Lynx to Cancer, with streamers in the NE, and a luminous patch in Gemini (all brightness 0 to 1). At 11.15 there was a well-defined yellow corona (brightness 2), quivering rapidly, occupying Cygnus, Hercules, Corona Borealis, Boötes, Canes Venatici, Leo Minor, Ursa Major, and Ursa Minor, also Auriga and Perseus. The needles were considerably disturbed all night, the disturbance reaching its maximum between 10 a.m. and 12 m.

February 22, and 23, 1883, 1.55 p. m. to 8.15 a. m.—At 11.55 the aurora consisted of indistinct patches and streamers in the NE., which at 12.15 a. m. had developed into a faint corona, centering in Camelopardalis. It was made of shifting streamers, which were short, except in the NW, and SE.—At 1 there was a broad, highly modified zone occupying large parts of the sky, made up

of twisted streaks, angular curtains and streamers, with some motion (brightness mostly 1, reach, ing 2 in some places). Two bands were well defined, one on the eastern edge from Leo through Leo Minor, Ursa Major, Draco, Ursa Minor and Draco again to Lyra, and the other on the west ern edge through Cancer, Canis Minor, Gemini, 5 Tauri, Perseus, and Andromeda. The zone had moved toward the W. at 1.15 and was not so well defined, while a band of indistinct shifting curtains ran from Orion's belt to Canis Minor ( $\alpha$ ) and curving back to  $\beta$  Tauri. At 2 a. m. a broad band ran from the ESE, in Hydra through Leo, Leo Minor, Lynx and Ursa Major, Camelonard alis, Ursa Minor, Cassioneia, and Andromeda to NW, in Pegasus. This was constantly changing its shape with rapid, twisting, whirling, and waving motion, shifting also from E. to W. and back again. It was tinged with shifting colors, pale green and rose (brightness 2 to 3). There were also unieter bands from the same starting points lying towards the SW., the lowest passing through the Hyades. The main aurora had faded to traces at 2.15, leaving large patches of luminous haze. while a narrow band (brightness 2) ran from Pegasus through Cygnus, Lyra  $(\alpha)$ , and Boötes  $(\alpha)$ . At 3 a. m. a narrow, twisted, shifting band, composed partly of streamers, passed close to the zenith from E., low in Bootes, through the tail of Ursa Major, Draco, Ursa Minor, Cephens, Cassi oneia, and Andromeda to the NW, in Pegasus (brightness 1 to 2), with two pale arched bands in the SW,, the lower from Pegasus, through Aries, Taurus (a), the head of Orion and Canis Minor (a), ending in the moonlight SE. It was much faded and broken at 3.16. At 1 a.m. there was a similar band, tinged with green and rose, starting high in the NW, in Perseus, passing through Auriga (d) Lynx, Leo Minor, and Coma Berenices, ending in the ESE,, shifting and way. ing. 4.15 found it broken and shifting, passing through (a) Aurigae, with some ill-defined patches and bands in the SW. Traces only were observed in the SE, at 5, and no more was seen till 8.15. when a rapidly waving band ran from Taurus through Auriga, Camelopardalis, and Ursa Minor to Boötes (brightness 1 to 2). The needles were considerably disturbed from 11 p. m. to 10 a.m. the greatest disturbance being at 2 a. m.

February 23 and 24, 1883, 11.55 p. m. to 11.17 a. m.—When the aurora was first noticed, shortly before midnight, Washington time (6.40 local), it was in the form of two faint, slightly arched bands in the NE, about 30° above the horizon. At 12.15 it was an arch of fine streamers, with its extremities bearing NW, by N, and ESE,, and its altitude about 30° (brightness 1). This band was essentially unchanged in character and position at 1 a. m., with an additional hazy band (brightness 1), from nearly the same starting points, passing through Leo, Leo Minor, Ursa Major, Draco, Ursa Minor, Cepheus, and Cygnus. This had disappeared at 1.15 to 1.20, leaving the first band, which had become more compact and brighter (brightness 1 to 2). At 2 a. m. there was a regular arch (brightness 1) from the ESE, in Virgo to the NNW, near β Cygni, through Coma Berenices, Boötes, Corona Borealis, Hercules, and Lyra (α). This was fading rapidly at 2.15 to 2.20. There was no aurora at 3 or 4, though faint and fugitive traces were noticed between the two hours. At 4.15 there were faint traces in E. and a band (brightness 0 to 1) from NW, in Pegasus through Andromeda, Perseus, and Auriga. From 5 to 5.20 a, m, there was a vellowish zone (brightness 1 to 2) with the bands in rapid waving motion from Orion to Boötes and Serrens through Gemini, Lyux, Ursa Major, and Canes Venatici. From 6 to 6.20 there was a band of streamers (brightness 0 to 1) vibrating rapidly from W. to E., running through Perseus, Cassioneia, Cepheus, Cygnus, Lyra, and Hercules. At 7.20 and 8.20 traces only were observed, and also at 9.17, when they were in the SE., white and shifting. At 10.17 there were curtains from NNW, to ESE., with streamers in Leo Minor. All were white, with occasional tinges of green and yellow, and changing form and position very rapidly. At 11.17 there were faint traces near the zenith, with faint streamers in the W. The needles were more or less agitated all night, the disturbance being extreme at 8 a. m., 9 to 9.30 a. m., and 2 to 2.40 p. m.

February 25, 1883, 12.15 a. m. to 9.17 a. m.—The aurora began as a faint bunch of streamers in the SE, at 12.15, and at 1 a. m. had developed into four bands of ill-defined curtains, forming a sort of zone in the SW,, with its starting points NW, in Pisces and ESE, in Hydra, the uppermost passing through Triangulum, Perseus, Auriga, Gemini, Cancer, and Leo, the lowest through Canis Minor, Orion, and Taurus, with slight waving motion (brightness 1). It had the same general character at 1.15 to 1.20, but was rather lower. From 2 to 2.15 it was nearly in the same position,

Leo through on the west. The zone had shifting eura. m. a broad Camelopard itly changing W. and back There were ssing through uninous haze. id Bootes at. lose to the zephens, Cassiched bands in Canis Minor m, there was seus, passing ting and waystined patches seen till 8.15. d Ursa Minor

of streamers tains, forming ra, the upperwest through same general same position, Lat the curtains were shifting and turning into bands (brightness 2 to 3). The lowest band beginning as a patch of curtains just above Sirius, and finally formed an arch (2,20), made up of short, ill-defined streamers, quivering slightly (brightness 3), rather brightly colored, green, yellow, and rose, passing just above Sirius and through \( \beta \) Orionis. The curtains broke partially into streamers and moved up towards the zenith, having developed at 3 a. m. into an elongated corona (brightness 1), centering towards the zenith, with its longest diameter NE, and SE,, nearly reaching the horizon at these points, the other streamers reaching as low as Arcturus in the NW, and Aldebaran in the SW. The streamers were uncolored and shifting. For the next half hour there was no definite arrangement of aurora, but the sky was covered with sinuous bands and scattered streamers all constantly changing position and brightness, the bands, as a rule, at right angles to the magnetic meridian, mostly E. of the zenith. At 4 a. m there were two or three broad shifting bands (brightness 1 to 2) from the SSE, in Virgo, spreading out through Leo and Ursa Major, forming an irregular corona at the zenith about 60° in width, with two paler bands from the same starting points along the SW, horizon through Canis Minor and Orion, ending in Taurus, NW, The corona had changed at 4.15 into a broad, shifting zone, ending in NW, in Taurus, with considerable waving motion in the NW. From 5 to 5.20 there was a broad band of waving curtains in the NE, from Pegasus through Lacerta, Cygnus, Lyra, Hercules, and Corona Borealis (brightness 1 to 2). From 6 to 6,20 there were two yellowish bands (brightness 1 to 2) in the SW, through Taurus, Orion, Auriga, Gemini, Cancer, Leo, and Coma Berenices. Traces only were observed at the next observation. At 8 to 8.20 a faint band (brightness 0 to 1) ran from Auriga through Lynx, Ursa Major, Canis Venatici, and Boötes, and the last faint traces were seen at 9.17 a.m. There was considerable disturbance all night.

February 25 and 26, 11,45 p. m. to 10,20 a. m.—At 11,15 p. m. there was a regular arch in the N.E., with its extremities bearing ESE, and NW., with its crown about 40° in altitude (brightness 0 to 1), remaining in the same position at 12. At 12.15 it was rising in altitude and had become brighter (1 to 2) in the NW., where it was tinged with rose, and sent up rather long streamers. From 1 to 1.20 the arch was of the same character, but lower, passing through Hercules, Corona Borealis, and Boötes (above a), ending in Virgo, with streamers in Cygnus (brightness 2 to 3). The arch was shifting, and tinged with green, yellow, and rose. At 2 a. m. there was a rather broad zone (brightness 2), with the starting points NNW, in Pegasus and ESE, in Crater, occupying Leo, Leo Minor, Canes Venatici, Ursa Major, Camelopardalis, Ursa Minor, Cepheus, Cassioncia, and Andromeda. This had drifted west at 2.15, leaving only a faint band in its original position, while the zone now passed through the square of Pegasus, the Pleiades, Perseus, Gemini, and Cancer. This began to grow twisted in the E. and developed into curtains which rapidly increased in brightness (brightness 3), showing some color beginning to whirl and spread toward the zenith and eastward. When this was reached the motion became very rapid, and the aurora formed a sort of spiral corona, made up of bands of curtains, centering round the zenith and covering nearly the whole sky. This moved last, and in fifteen minutes was reduced to large hazy patches, with bright streaks in the NE. At 3 a, m, there was a short arch (brightness 2 to 3) from the E, low in Boötes to NNW, in Cygnus, through  $\varepsilon$  and  $\beta$  Cygni, Hercules, and Corona Borealis. A second arch appeared above this at 3.15, when both were broken into fine streamers, which shifted and developed into homogeneous bands again before 3.20. At 4 a. m. there were bunches of streamers (brightness 2) in the place of the arch at the last observation, with traces of a very faint zone across the zenith. From 4.15 to 4.20 there were only traces in the E. and SE., with much diffused luminosity all over the sky. From 5 to 5.20 there were only traces again in the S. No more was seen till 7 a.m., when there was a belt of waving bands through Taurus, Orion, Gemini, Leo, Ursa Major, Canes Venatici, Coma Berenices, and Boötes, from NW. to SE., with a band of streamers (brightness 1 to 2) running N. to SE, through Cassiopeia, Cepheus, Cygnus, Lyra, Draco, Hercules, Corona Borealis, and Boötes, vibrating rapidly from W. to E. Traces alone were observed in the SE. from 8 to 8.20. At 10.20 there was a faint white arch across the zenith from the SE, to NW. There was no marked disturbance of the needle till 1 p. m., when it was violent, but of short duration.

February 27, 1883, 12.15 a. m. to 10.17 p. m.—The weather cleared between 12 and 1 a. m., disclosing an arch (brightness 1 to 2), partly obscured by clouds in the NE., passing through Arcturus and α Corone Borcalis, with streamers beginning to develop at 1.20 m and above Cygnus. At 2

a. m. two or three broad singons tands were to be seen through the haze crossing the zenth from NW, to SE,, one through Cassiopeia and one through Ursa Major. From 2.15 to 2.20 there was a zone of broad bands east of the zenith, partially obscured, especially near the horizon, coming up through Leo, with the upper band through Ursa Major and Bootes (a) (brightness apparently 1 to 2). At 3 a.m. there was a zone of broad bands with the starting points alone obscured in the NNW. and ESE., occupying Leo, Leo Minor, Ursa Major, Draco, Ursa Minor, Cygnus, and Lacerta (brightness 1 to 2). From 3.45 to 3.20 it was brighter (brightness 2) and west of the zenith, occupyin-Andromeda, Triangulum, Aries, Taurus, Perseus, Auriga, Gemini, and Aries. At 4 a. m. nearly the whole sky was covered with broad, shifting, sinuous, hazy bands running generally NW, and SE, brightness 1), with some brighter streaks (brightness 2) in the E. This had all condensed at 1.15 to 4.29 into a broad arched band (brightness 2) in the NE, from Virgo to Pegasus, passing through Boötes, Serpens, Hercules, Lyra, and Cygnus, sending up streamers in the NW, and do. veloning into a sort of zone. From 5 to 5.20 there was a quiet band (brightness 0 to 1) running through Taurus, Orion, Canis Minor, and Leo into Virgo. Traces only were seen at the next observation, but from 7 to 7.20 there was a quiet band (brightness 0 to 1) through Cassiopeia, Cepheus, Draco, Hercules, and Boötes. A slightly waving band at 8 to 8.20 ran through Orion, Gemini. Cancer, Lynx, Ursa Major, and Leo (brightness 1). At 9.17 a. m. there was a white, quiet arch over the southern horizon from SE, to WNW,, with the crown at an altitude of about 15 and a broad, quiet, irregular band from the E. through Lacerta, Cepheus, Ursa Minor, Ursa Major, and Lynx to Cancer (brightness 1). At 10.17 there was a corona elongated from ESE, to WNW, occur pying Sagitta, Hercules, Lyra, Draco, Ursa Major, Leo Minor, and Gemini in the E., S., and W. 41 underwent a slow, constant change of form and position (brightness 1). There were also long streamers in Lacerta, Andromeda, Triangulum, Persens, and Arius, and a broad, luminous band near the horizon from the S, to SW. The magnetic needles were considerably disturbed all night.

Fibruary 28, 1883, 1.15 a. m. to 5.20 a. m.—The sky was covered all night with clouds, which at intervals broke away and became hazy enough to allow some of the stars to be seen. Between 1 and 2 a. m. bright bands in pretty active motion could be seen through the clouds, particularly in the SE, and NW., where there was a bright loop with its convexity towards the zenith. At 2 a. m. a band of bright curtains, waving rapidly, could be seen through the clouds in the NE., at an altitude of about 30°. From 2.15 to 2.20 there were twisted streaks and streamers from the NW. to SE., and partial coronas, bright and shifting, seen through the clouds. Bands could be seen through the clouds in the SW., which were less obscured from 4.15 to 4.20, so that the upper was observed to pass through a Leonis, α Orionis, and α Tauri. This faded rapidly, while a zone observed by the haze developed from the SE, towards the zenith. The clouds then thickened up so that traces only were seen in the S, at 5 to 5.20. The needles were disturded violently all night.

February 28 and March 1, 1883, 11,30 p. m. to 10,40 a. m.—The sky cleared off while the twilight was still bright, and only the large stars were visible, and there appeared a bright aurora, probably a continuation of yesterday's, as when first seen it crossed the zenith. It was a yellowish, twisted band, which ran from the ESE, to WNW., and appeared shifting and agitated, developing gradually into a broad zone, while at 12.15, when the sky was dark enough for proper observation, occupied Cancer, Cassiopeia, Ursa Minor, Auriga, Andromeda, and Pegasus, and was in rapid motion (brightness 2). At 1.15 to 1.20 the zone was west of the zenith and somewhat obscured by clouds and haze, especially at the starting points. It was observed to pass through Gemini, Au riga, Perseus, and Andromeda (brightness 2), shifting and waying. At 3 to 3.15 it had subsided to quiet bands (brightness 1) from Leo through Canis Minor, Orion, Taurus, and Aries. At 4.17 there was a quiet arch over the southern horizon from SE, to NW., with its crown at an altitude of about 18% or 20%, and a zone of broad bands from the SE, to NW., occupying most of the sky between Cygnus and Lynx, and drifting slowly towards the W. (brightness of all 3). Traces only in the N, and W, were visible at the next hour. At 6.17 there was a zone of broad bands (brightness 3 to 4) from NW, to SE,, stretching in width between Ursa Major and Cygnus, rapidly changing form and position, and bounded on the SW, edge by a broad curtain, passing through Serpens, Boötes, Corona Borealis, Leo Minor, and Gemini, vibrating rapidly in both directions, and showing brilliant pink, green, and yellow, with also a broad, quiet band from the Pleiades to Cygnus, near the northern horizon. At 7 to 7.20 there was a band of rapidly vibrating streamers (brightness ! ie zenith from

to 2) from Andromeda through Cassiopeia, Cygnus, Lyra, and Draco to Canes Venatici, and another waving band from Cygnus through Lyra, Herenles, Corona Borealis, and Boötes to Leo. This land subsided to traces in the E., S., and W. at the next hour. Waving bands (brightness 0 to 1) stretched through Aries, Taurus, Gemini, Auriga, Ursa Major, Leo Minor, Leo, and Cancer, at 9 to 9.20. At 10.17 there were faint traces near the southern horizon and pale streamers in the E., and the last traces were seen about 10.40 fading in the dawn. Vesterday's magnetic disturbance continued with uninterrupted violence.

March 1 and 2, 1883, 11.45 p. m. to 11.17 a. m.—The aurora appeared to be fully developed as anon as it grew dark, and was probably a continuation of vesterday's aurora. It first appeared as two streaming bands, starting near the horizon (southeast) and reaching nearly to the zenith. At 12 midnight two parallel bands of curtains crossed the zenith from SE, to NW. At 12.15 these were reduced to bunches of faint streamers in the SE, and NW., which soon rose and developed into curtains across the zenith. At 1 a, m, there was a narrow band of waving curtains (brightness 1, starting in Virgo, E. by S., running through the sickle of Leo and doubling back through Leo Minor, Ursa Major ( $\alpha$  and  $\beta$ ), Draco and Cygnus ( $\alpha$ ), with hazy bands spreading from Pegasus an through Cassiopeia to the zenith. At 1.15 to 1.20 these had developed into a broad shifting zone, edged with curtains (brightness 2 to 3), starting ESE, in Leo and NW, in Pegasus; in breadth extending from  $\alpha$  Aurigae to  $\beta$  Ursae Majoris. At 2 a.m., rising from the same starting points, bands (brightness 1) and curtains (brightness 2) covered the whole sky from the eastern horizon to Auriga. The whole was constantly shifting, and brightest near the zenith, where it formed a sort of elliptical corona. At 2,20 this was reduced to one main band in the NE, from Pegasus NW, to Virgo ESE, through Cygnus (α), Lyra (α), Corona Borealis and Boötes (α), and indefinite (0 to 1) bands spreading up from each end towards the zenith. The band soon devel aped into three, the middle the brightest, and colored especially with a pink approaching salmon color. It was in rapid lateral motion from the NW, and all was changing rapidly. At 3 a. m. it was reduced to a few bands low in the NE. At 3.15 to 3.20 there was a band of curtains, making a loop in the NW., coming up from Pisces through Andromeda, Cygnus and Lyra, with other indistinct bands in the E. The loop rose and became a twisted band across the zenith, with tinges of the usual colors. At 4 a. m. most of the sky was covered with streaks (brightness 1 to 2) and broad hazy bands radiating from near the horizon in the NW, and SE. At 4.15 there was a diverging sheaf of bands in the NW, in Pisces, Triangulum and Taurus, and a broad band along the northern horizon to  $\alpha$  Lyrae and then sweeping up almost in a circle through Draco, Ursa Minor, Leo Minor, and Leo to Virgo in the E. by S. and drifting rapidly westward (brightness 1 to 2. At 3 to 3.20 there were two bands (brightness 2 to 3), the upper quiet and the lower with streamers vibrating rapidly from W. to E., changing color from rose to yellow and green, running from Taurus through Orion, Canis Mipor, Gemini, Cancer, Leo Minor, Leo, Coma Berenices and Boötes to Virgo, from NW, to SE. At 6 to 6,20 there were two quiet bands (brightness 0 to 1), one from Serpens through Boötes, Coma Berenices, Leo, Cancer, Auriga, Taurus, and Aries, and the other from Andromeda through Cygnus and Hercules, with detached patches in Canes Venatici, Ursa Major and Camelopardalis. Traces only were observed at the next two hours. At 9.17 there was an extensive zone (brightness 0 to 1), running E, and W., about 50° broad, drifting slowly southward, with an irregular band near the SW, horizon from W, to SSW,, and quiet streamers (brightness 0 to 1) in Auriga, Perseus, Triangulum, Andromeda, Pegasus and Vulpecula. Traces only were seen at the next two observations in the SW, and N, at 10.17, and in the form of a shifting corona, fading in the dawn at 11.17. The magnetic disturbance still continued.

March 2 and 3, 1883, 11.45 p. m. to 10.17 a. m.—The twilight was so bright that only the largest stats were visible when the aurora was first seen. It began with streamers in the SE., which soon developed into a twisted band across the zenith. At 12.15 the waving band was in the same position (brightness 2 to 3), yellowish green in color and tinged with rose, and soon broke into four bands, extending 40° each side of the zenith. At 1 a. m. a moderately wide zone (brightness 1 to 2) crossed the zenith, starting ESE. in Leo and NW. in Pegasus, extending in width from \( \alpha \) Aurigae to \( \alpha \) Ursa Majoris, while two outlying bands from the same starting points (brightness 2) ran through Canes Venatici, Ursa Major (n), Corona Borealis, Boötes, Draco, Lyra, and Cygnus. The whole was narrower and fading at 1.15 to 1.20. It was brightest near the starting points and

drifted eastward, much obscured by clouds. At 2 a.m. a zone about 60° broad, crossing the zenith from SE, to NW, was visible through the thin clouds (bright aess apparently 1 to 2). At 2.15 to 2.20 the sky was clearer, though the starting points were still obscured. The shifting bands were nll west of the zenith, the crown of the lowest passing through a Tauri. A hazy band was propagating rather rapidly from the SE., and the whole faded quickly and brightened up again. At 2.45 these bands in the W. were still pale, but somewhat convoluted. Suddenly the whole shot in to the zenith with lightning rapidity, burning very bright (3 to 4), and developing exceedingly rapid motion, both waying and whirling, with rapid changes of color and brightness. It passed the zenith in about two minutes, forming a semi-corona, first on the west side and then on the east, The motion was mostly from the NW., and the colors, though delicate, were exceedingly bright. They were apple-green, pale yellow, and rese-pink, in the usual order, the latter especially bean, tiful. In less than tive minutes the motion subsided and the aurora faded, leaving the sky nearly covered with hazy, spiral, and sinuous bands (brightness mostly 1, some brightness 2), appearing to start from the SE and NW., forming a sort of vortex round the zenith, circling and waying slowly, as it was seen at the 3 a. m. observation. At 3.15 to 3.20 there was in addition a bright loop in the NW., seen through the clouds, which gradually shifted and faded, breaking into luminous patches. At 4 a.m. all was gone except a bright glow in the NE, showing through the clouds: which at 4.15 to 4.20 could be seen to be an arched band. A shifting broad zone (brightness 0 to 1) covered most of the sky, and began to develop spirals in the N. At 5 to 5.20 a slowly-waying band (brightness 1 to 2) ran from Triangulum through Andromeda, Cassiopeia, Cepheus, Ursa Minor. Draco, and Boötes. Traces only were seen at the next observation. At 7 to 7.20 a belt of quiet bands (brightness 0 to 1) ran from Taurus through Auriga, Gemini, Lynx, Ursa Major, Leo Minor, Cames Venatici, and Coma Berenices to Virgo. Only traces were seen at 8. At 9.17 there was a broad arch from the NW, to SE,, with its crown at an altitude of about 18°, and a broad, irregular, striated arch from the SE, to NNW, through Lyra, Draco, Ursa Major, Lynx, and Gemini tall brightness 0 to 1). This had faded to traces at 10.17. This aurora was probably a continuation of last night's, as it appeared highly developed at dark, and the magnetic disturbance still continued, though its violence was greatly abated.

March 4, 1883, 12.15 a, m, to 10.17 a, m,—Before the twilight was faded there was a faint arch in the NE., whose extremities bore ESE, and NW., with its crown at an altitude of about 20. At i a, m, there was a regular arched band (brightness I) in the NE, from ESE, in Leo through Coma Berenices, Boötes, Corona Borealis, Hercules, Lyra, and Cygnus, with streamers in Cygnus, which had developed at 1.15 into the upper band of a zone of three bands, passing through a Ursa Majoris. At 2 a. m. there was an extensive zone (brightness 1 to 2) starting ESE, in Leo and NNW, in Pegasus, with its eastern bands in the position of the aurora last noted, and the main body of the zone crossing the zenith, going only 3° or 4° west of Polaris. Here it began to wave and circle, while the band through n Ursae Majoris was now made up of short streamers, vibrating rapidly from E. to W., and slightly tinged with the usual colors. At 2.15 the main position still circling had reached α Aurigae in the W., and the belt of streamers had become a broad sinuous band in rapid serpentine motion from the SE,, again breaking into longer streamers, vibrating from NW, to SE. The western portion faded out in about five minutes, while the eastern subsided to quiet bands (brightness 1). At 3 a. m. nearly the whole sky was covered with hazy zone bands (brightness  $\theta$  to 1) from  $\alpha$  Lyrae to Orion's belt, thinnest near the zenith and most namerous in the W. At 3.15 to 3.20 these were condensed to a broad shifting band (brightness 2) from Leo  $(\beta)$  in the ESE, to Pegasus in the NW, through  $\gamma$  and  $\mu$  Leonis, Leo Minor, Lynx, Auriga, Perseus, and Andromeda. At 4 a. m. there were two well-defined arched bands (brightness 0 to 1) in the NE., the upper broad and the lower narrow, starting from Triangulum to Serpens through Pegasus. Cygnus ( $\varepsilon$  and  $\beta$ ), and Hercules, with much diffused luminosity, reaching up to the zenith. At 4.15 to 4.20 the bands were twisted and broken, with a few pale streamers in the ESE, soon disappearing, and evanescent twisted streaks near the zenith. At 5 to 5.20 one band ran from Aries through Triangulum, Andromeda, Cassiopeia, Cygnus, Lyra, Draco, Hercules, and Serpens, and another short band from Taurus through Auriga and Ursa Major (brightness 0 to 1). At 6 to 6.20 there were traces only in the S. At 7 to 7.20 a slowly waving band (brightness 1 to 2) ran from Taurus (brough Orion, Gemini, Cancer, Leo, and Coma Berenices. At 8 to 8.20 there was a ssing the zenith o 2). At 2,15 to ting bands were band was propa. d up again. At he whoic shot un ing exceedingly ness. It passed then on the east, ceedingly bright, especially bean. g the sky nearly ess 2), appearing ing and waving ddition a bright aking into lumiough the clouds: orightness 0 to 1) wly-waving band us, Ursa Minor, 0 a belt of oniet lajor, Leo Minor, 9.17 there was a broad, irregular,

At ESE,, soon disap-1 ran from Aries nd Serpens, and 0 to 1). At 6 to tness 1 to 2) ran 8.20 there was a quiet band from Pegasus through (Orion, Gemini, Cancer, Leo)  $\delta$ , Cygnus, Aquila, and Serpens (brightness 0 to 1). At 9.17 there was a diffused arch from the SE to NNW., with its crown at an altitude of about 20°, with faint streamers in the NNW. At 10.17 there was a faint trace of an arch across the zenith from SE, to NW. Only slight magnetic disturbance was noticed.

March 5, 1883, 12.15 a.m. to 8.20 a.m.—At 12.15 (about 7 a.m. local) there was a faint arch in the NE., with its extremities bearing ESE, and NE., and the crown at an altitude of about 45%. with streamers in the NW. At 1 a.m. a broad twisted band (brightness 1 to 2), shifting and waving, crossed from ESE, in Leo to NNW, in Pegasus through Leo Minor, Ursa Major, Lynx, Ursa Minor, Cassioneia, Cepheus, and Lacerta. It had drifted west to Auriga and Gemini at 1.15 to 1.20, and was brighter (brightness 2), and gradually spread towards the E., beginning to gyrate in the SE. in indistinct curtains. At 2 a.m. there was a rather narrow zone, with some of the bands approaching the curtain form from nearly the same starting points, broadest from  $\zeta$  Ursac Majoris nearly to a Aurigae, with the bright portion mostly NE, of the zenith, and waving somewhat. It was broader at 2.15 to 2.20, and not so bright (brightness 1), and the bands were closer together, with less motion. At 3 there was a very broad zone (brightness 1 to 2) from nearly the same starting points, in width from  $\alpha$  Lyra and  $\alpha$  Boötis to  $\alpha$  Canis Minoris and  $\alpha$  Tami, brightest on the eastern edge and in the part west of the zenith, with a slight waving motion. At 3.15 to 3.20 the edges had faded and all was slowly fading except the extreme NE, bend. From 4 to 4.20 there were remains of the aurora (brightness 0 to 1) in essentially the same position, which had nearly all faded, except the western band, at 4.20. At 5 to 5.20 a quiet band (brightness 2) ran through Taurus, Gemini, Orion, Cancer, Leo, Coma Berenices, and Boötes. At 6 to 6.20 a corona (brightness 1) covered nearly the whole sky, centering in Ursa Major, and in rapid motion. Faint traces of this still remained at 7 to 7,20, and traces were again seen in the NW, and SW, at 8 to 8,20, After this the weather became cloudy. The magnets were comparatively quiet all night.

March 6, 1883, 3 a. m. to 9.14 a. m.—The aurora may have begun a little earlier, as there was a bank of hazy stratus clouds in the NE., but the first that could be recorded with certainty was at 3 to 3.20, when there were ill-defined luminous patches in the E., partly obscured by clouds, followed by exceedingly faint vertical streaks, first one and then three, streaming up from the SE, towards the zenith with a better defined streamer close to the horizon in the NNW, at 3.20. At about 3.40 these had developed into a band (brightness 1) from the clouds in the ESE, across the zenith to α An aromedae in the NNW, which broadened into a zone, and at 4 to 4.15 was reduced to hazy traces about 30° in width near the zenith. These gradually became brighter in the SE, streaming up through Leo (β) to the zenith. At 5 to 5.20 only traces were observed, a little south of the zenith. At the next observation none was seen, but at 7 to 7.20 a quiet band (brightness 0 to 1), from Taurus through Orion, Gemini, and Leo. At 8 to 8.20 a. m. there were traces in NW, and SW. At 9.17 there was an arch from NW, to SE, with its crown about 20° above the southern horizon and traces in the NNW. No more was seen after this, though the sky was clear. There was a slight magnetic disturbance, beginning at 9 a m.

March 7, 1883, 12.15 a, m, to 10.17 a, m.—At 12.15 there were faint streamers in the E., which at 1 a. m. had developed into a twisted band of streamers (brightness 1), from ESE, in Hydra, through Leo, Lynx, Camelonardalis, and Cassioneia, swinging round into Perseus somewhat in the form of a corona, with slight motion. The band was in the same position, with a well-defined semi-corona SW, of the zenith, reaching into Auriga and Gemini, with the band extending down into Andromeda NNW., the whole soon fading. At 2 to 2.20 there was an arch of shifting streamers (brightness 0 to 1) in the SW., much obscured by haze and clouds, especially near the horizon, reaching an altitude of about 30°, and passing through Leo, Cancer, Gemini, and Taurus. At 3 a. m. there was a somewhat irregular corona, connected with the horizon by narrow streaks ESE, and NNW., and made of curtains (brightness 1 to 2) running round through Leo Minor, Lynx, Gemini, Taurus, Aries, Andromeda, Cassiopeia, Cepheus, Draco, and Ursa Major, surrounding hazy curdled streaks (brightness 0 to 1) about the zenith, with slight motion. At 3.15 to 3.20 only the western portion remained, forming a sort of zone, combined with a semi-corona, and slowly shifting. At 4 there was merely an ill-defined arch of streamers in the SW., which at 4.15 had become three or four shifting bands of curtains, flickering from the extremities towards the center (brightness 2 to 3), tinged slightly with the usual colors. This soon tose towards the

H. Ex. 44----55

zenith, at length forming a complete corona of curtains (brightness 1), elongated towards the horizon, and brighter (brightness 2) in ESE, and NNW., with considerable motion at 4.20. At 5 to 5.20 a band of streamers, in slow metion from W. to E., ran through Taurus, Auriga, Gemini, Cancer, Leo, and Virgo, with short, broad, quiet bands from Virgo through Boötes, Serpens, Corona Borealis, Coma Berenices. Canes Venatici, Leo Minor, and Ursa Major (brightness 2 to 3). At 6 to 6.20 a band (brightness 1) ran through Perseus, Cassiopeia, and Cygnus. At 7 to 7.20 only traces near the zenith were seen. At 8 to 8.20 there were several parallel bands in the S., 15° to 50° above the horizon (brightness 0 to 1). At 9.17 there was an arch in the S. (brightness 0 to 1) from SE, to NW., with an altitude of about 20°, with faint curtains in the N, and NE, and a few faint streamers centering towards the zenith. At 10.17 traces of the arch still remained, and other traces in the W., N., and near the zenith. There was a magnetic disturbance from 1 a. m. to 1 p. m., reaching its maximum at about 12 m.

March 8, 1883, 12.15 a. m. to 9.17 a. m.—The aurora was first noticed at 12.15 (about 7 p. m. local), when the twilight was still bright, as a band crossing from SE, to NW., passing about 200 SW, of zenith. In the next three observations there was much haze and hazy clouds, obscaring the stars. At 1 a.m. a broad shifting zone crossed the zenith from WNW, to ESE,, showing through the haze (brightness 1 to 2). At 1.15 to 1.20 it was narrower, and passed 15° to 20° SW. of the zenith. At 2 a. m. there showed through the hazy cloud in the SW, a regular arch (brightness 2), reaching an altitude of about 20°. This was gone at 2.15 to 2.20, and a hazy band crossed about 15° SW, of the zenith. At 3 a. m. there was a broad zone about 120° in width from SE, to NW, (brightness 1 to 3). It was brightest on the edges, especially in the W., where there was considerable motion and tinges of the usual colors, all obscured by the haze. At 3.15 to 3.20 ii was mostly confined to the NW., where it formed bright shifting loops, with their convexity towards the zenith. At 4 a broad waving and shifting zone crossed the zenith (brightness 1 to 2) from a broad origin, NNW, to NW, by N., to ESE., the starting points in Virgo and Andromeda, Triangulum and Aries, the eastern edge passing through Coma Berenices, Canes Venatici, Ursa Major, Ursa Minor, and Cassiopeia, and the western through Leo Minor, Lynx, Auriga, and Perseus, with an arched yellow band (brightness 2 to 3) to the NE. through Cygnus (a), Lyra (a), Corona Borealis, and Virgo. At 4.15 to 4.20 it was in nearly the same position, but fading and shifting. The eastern edge of the zone appeared fimbriated. At 5 to 5.20 a slowly waying band (brightness 1 to 2) ran through Taurus, Auriga, Ursa Major, Canes Venatici, Coma Berenices, Boötes, Corona Borealis, and Draco. Traces only were observed at 6 to 6.20. At 7 to 7.20 bands and patches (brightness 0 to 1), without motion, covered the southern half of the sky. These had faded to mere traces near the southern horizon at 8 to 8,20. And traces only in the SW, and N, were seen at 9,17. None were seen at the next observation, but the sky then became cloudy, so that the end cannot be determined with certainty. A magnetic disturbance commenced about 3 a. m., and continued the rest of the night, reaching its greatest violence at about 9 a. m.

March 9, 1883, 1.15 a. m. to 6.20 a. m.—Very early in the evening, while the twilight was still bright, a patch of aurora appeared in the SE, near the horizon, but soon disappeared, and no definite aurora was seen till 1.15 to 1,20, when indistinct horizontal bands appeared in the NE., beginning gradually to develop in the ESE. At 2 a. m. a barely perceptible band crossed the zenith from ESE, to NNW., through Leo, Ursa Major, Camelopardalis, and Cassiopeia, and was in nearly the same place at 2.15 to 2.20, beginning to shift a little towards the W. At 3 a kezy band (brightness 1) ran from the ESE, in Virgo to the NNW, in Andromeda through Leo, Ursa Major (a and தி, Camelopardalis and Cassiopeia, which at 3.15 to 3.20 was paler, and sent a band through Cancer, Taurus, and Aries. At 4 a.m. there were merely traces in nearly the same position, but at 4.15 to 4.20 there was a hazy band nearly 1 in brightness starting close to  $\alpha$  Virginis in ESE, through  $\delta$ , Leo (3 and 8), Leo Minor, Lynx, Auriga, and Perseus, ending in a series of short, ill-defined streamers in Andromeda NNW. At 5 to 5.20 a quiet arch (brightness 1) ran from Taurus, through Orion, Gemini, Leo, and Boötes. At 6 to 6.20 there was a bright corona (2 to 3), centering in Ursa Major, on the edges vibrating rapidly from W. to E., and in the center whirling rapidly. Traces were seen at the next two observations. The magnets were quiet until about 12 m., when there was a violent disturbance, lasting only three hours, and reaching its maximum at 1 a.m.

March 10, 1883, 1.30 a.m. to 9.17 a.m.—Evanescent traces were noticed in the N. about 4.30 a.m.,

towards the tt 4.20. At 5 triga, Gemini, sites, Serpens, intness 2 to 3). At 7 to 7.20 ands in the S., S. (brightness and NE, and till remained, rbance from 4

and again at 2 a. m. in Cygnus in the YW. At 2.15 to 2.20 there was a zone of three shifting bands (brightness 0 to 1) in the NE., through Cygnus, Lyra, Corona Borealis, and Boötes (a) into Virgo. At 3 to 3.20 there was a broad zone, shifting and changing in brightness from 0 to 1 to 1 to 2, crossing the zenith from ESE, in Virgo to NNW, in Pegasus, reaching in breadth from  $\beta$  and  $\gamma$ Diraconis nearly to \alpha Auriga. At 4 a. m. two bands (brightness 1 to 2) ran from the ESE, in Virgo to the NNW, in Andromeda, through Boötes, Corona Borealis, Draco (# and p), and Hercules, with a bright patch growing hazy and fading out towards the zenith in the NW., occupying Andromeda, Perseus, and Cassiopeia. This had developed at 4.15 to 4.20 into a broad, shifting zone (brightness 1 to 2), starting from the same point in the NNW, and forming a much convoluted mass in the E. in Aquila and Boötes, while the western edge ran through Boötes, Ursa Major, Ursa Minor, Camelopardalis, and Cassiopeia. At 5 to 5.20 a.m. a quiet band (brightness 1) ran from Aries through Triangulum, Andromeda, Cygnus, Lyra, Hercules, and Corona Borealis. At 6 to 6.20 the band was in nearly the same position, but brighter (1 to 2), and had a few streamers in Corona Borealis. At 7 to 7.20 there were merely traces in the N. and NE. At 8 to 8.20 a broad band (brightness 0 to 1) crossed the zenith from Orion to Aquila, through Auriga, Lynx, Ursa Major, Draco, and Hercules. At 9.17 a.m. there was a broad diffused arch in the south from ESE, to WNW., reaching an altitude of about 200, and a faint corona clongated from E. to W., occupying Cygnus, Ursa Minor, Lynx, Gemini, Lyra, Draco, and Ursa Major, and a short arch from E. to N., passing into Cassiopeia (brightness of all 0 to 1). There was a slight magnetic disturbance, lasting from 9 a. m. to 2 p. m.

March 11, 1883, 2 a. m. to 9.17 a. m.—Traces in the ESE, began to assume a definite form at 2 a. m., faint streaks streaming up to Virgo. At 3 a. m. the streak was very small, but at 3.15 to 3.20 better defined and longer, reaching into Boötes and Corona Borealis. At 4 a. m. a broad, hazy, striated band, almost a zone (brightness 1), ran from ESE, in Virgo to NNW, in Andromeda, through Coma Berenices, Canes Venatici, Ursa Major, Camelopardalis, and Perseus, and had drifted W. at 4.15 to 4.20 so as to pass through β and δ Leonis and Auriga. This had expanded into a broad zone at 4.45, but again contracted to a band at 5 to 5.20, crossing the zenith from cancer through Gemini, Auriga, Lynx, Camelopardalis, Ursa Major, Draco, Lyra, and Hercules. At 6 to 6.20 there were merely traces in the S.—At 7 to 7.20 a band of streamers (brightness 1 to 2), vibrating rapidly, passed from Taurus through Perseus, Cassiopeia, Cepheus, Cygnus, and Lyra. At 8 to 8.20 extensive traces crossed the southern sky. At 9.17 there was an arch in the 8. from SE, to NW., reaching an altitude of about 20°, with a short streamer in the NW, and traces of an arch running from ESE, to WNW, through Lyra, Draco, Ursa Major, and Lynx (brightness 6 to 1). There was a magnetic disturbance between 7 and 11 a. m., reaching its maximum at about 8 a. m.

March 12, 1883, 3.40 a. m. to 9.17 a. m.—At about 3.40 a. m. (10.30 local time) there were three or fear faint streamers in the N. in Andromeda and Cygnus, but at the regular observation at 4 a. m. the sky was too cloudy to allow any to be seen. At 4.15 traces of a pale zone or clongated corona could be seen through the clouds, but at 5 to 5.20 the sky was sufficiently clear to display a quiet band (brightness 0 to 1) from Boötes, through Canes Venatici, Ursa Major, and Lynx, to Auriga. Traces were seen in the S. at 6 to 6.20. The sky was partially cloudy at the next two observations, but clear enough at 9.17 to show an clongatêd corona (brightness of 1), longest from SE. to N. W., where it reached the horizon, centering at the zenith, and made up of a long, slender ray, with slight motion, about 40° long on the sides of the corona. Increasing light and clouds prevented observation of the end of the aurora. The needles were slightly disturbed from 9 to 10 a. m.

March 13, 1883, 1.10 a. m. to 9.17 a. m.—The weather was cloudy early in the evening, but between 1 and 1.15 a. m. disclosing a brilliant display in the western sky still bright with the twilight in the form of an arch of short streamers vibrating from the extremities towards the crown. The ends bore NW, and S. about 20° above the horizon, while the crown reached an altitude of 35° close to a Tauri, while below the arch were irregular curtains, the whole tinged with the usual colors (brightness 2). The streamers suddenly fused together and the motion became rapid, bright colors—particularly rose—developed in the S. with rapid changes of color and brightness, becoming a broad zone of bands and curtains in very rapid motion (brightness 2), and in a few seconds reached the zenith and passed it, forming a semi-corona, and faded to hazy bands

covering nearly all the sky. In about two minutes it began to develop again in the NW., reaching brightness 3, with bright colors and rapid motion in Cassiopeia, and some reached the zenith. forming an elongated corona of curtains in very rapid motion in several concentric rows rapidly fading. At 2 a. m. a band of short streamers ran from  $\alpha$  Hydrae through Orion's belt to the clouds in the NW, while there was a broad hazy band just above this, and one long semi-corona the western half of which was a broad, sinuous band, the eastern a fan of streamers, the longest about 30°, near the zenith, centering about the middle of Camelopardalis and extending from Leo in the ESE, to Cassiopeia in the NW. The streamers were replaced by a hazy band at 2.15 to 2.20, with traces of the corona which were gradually growing more distinct (brightness of all 0 to 1). At 3 a. m. there were three hazy arched bands in the SW,, and a narrow zone from the clouds in the ESE, to Cassioneia NNW, in breadth, from \(\lambda\) Draconis to \(\alpha\) Aurigae, with a semi-corona E, of the zenith, mostly in Bootes, Canes Venatici and Ursa Major (brightness 1). At 3.15 to 3.20 there were only traces of the zone and corona, while the bands in the SW, were less distinct (brightness 0 to 1). At 4 a m there was a wavy broad zone (brightness 1 to 2) brightest on the eastern edge. with the starting points near  $\alpha$  Virginis in the ESE, and  $\alpha$  Arietis in the NW., with the western edge close to the hozizon and the eastern through Corona Borealis, Draco, Cepheus, Cassioneia and Andromeda, composed of bands and curtains, with some motion on the eastern edge. At 4.15 to 4.20 all was west of the zenith (brightness 1) and rapidly fading from above towards the horizon. At 5 to 5.15 a band of curtains and streamers rapidly vibrating and waving (brightness 1 to 2) ran from Andromeda through Lacerta, Cygnus, Lyra and Hercules. At 6,20 a band (brightness 0 to 1) ran from Gemini to Lynx and Ursa Major. At 7 to 7.20 there were traces only in the SW. At 8 to 8.20 the sky was nearly covered by a corona centering in Ursa Major and extending to a band about 15° to 20° above the horizon. There was no motion near the zenith, but a few bands of streamers in the N. and NW. (brightness 2 to 3), in Auriga and Cassiopeia, were vibrating very rapidly. The last faint traces were seen in the NW, at 9.17. The needles were disturbed from 1 to 8 a. m., the disturbance reaching its maximum at the last hour.

March 14, 1883, 1.15 a. m. to 9.17 a. m.—At about 1.15 a. m. there was noticed a faint, narrow. quiet arch in the NE, from ESE, to NNW, just below ε Cygni through Boötes (close to a), Corona Borealis  $(\alpha)$ ,  $\alpha$  Lyra and Cygnus; at 1.20 rising and changing into streamers in the NNW. At 2 a. m. there was a narrow, indistinct, hazy zone from ESE, in Virgo to NNW, in Andromeda. stretching in breadth from  $\delta$  Ursæ Majoris to  $\alpha$  Persei. This at 2.15 to 2.20 was wholly W, of the zenith, occupying Andromeda, Perseus, Cassiopeia, the upper part of Taurus, Auriga, Gemini and Leo (brightness 0 to 1). At 3 a.m. there was a broad zone of two chain bands, about 300 apart (brightness 2), starting in the ESE, in Virgo and the NNW, in Aries, and extending from the middle of Camelopardalis near the zenith to about 2° below a Canis Minoris and the SW., altitude about 25°, with a slight waving motion in the ESE. At 3.15 to 3.20 it was not so bright (brightness 1) and the western edge was unchanged, but the whole had spread E, so as to cover nearly the whole sky to within 10° of the horizon in the N.E., and was very sinuous in the N. At 4 a.m. there was a hazy loop in the N. and NE. (brightness 1) from Aries near a through Triangulum, Andromeda, Cepheus  $(\alpha)$  and Draco, bending back near  $\theta$  Draconis through Herenles  $(\epsilon)$ , Lyra (β), Cygnus, and Andromeda. At 4.15 to 4.20 there were pale traces of the loop from Aries up through Cassiopeia towards the zenith, with a regular arch in the SW, from ESE, near a Virginia to the moonlight in the NW., with its crown near \alpha Hydra, and a belt of three or four bands in the NE., from N. to E., with its crown near \(\beta\) Cygni (brightness 0 to 1). At 5 to 5.20 a. m. a quiet band (brightness 0 to 1) ran from Taurus through Perseus, Andromeda, Cassiopeia, Cepheus, Cygnus, Lyra and Hercules. At 6 to 6,20 auroral bands covered nearly the whole sky. The brightest part was in the N. and NE, where it had a rapid motion. Round the zenith were only a few faint, quiet bands (brightness 1 to 2). There were extensive traces at 7 to 7.20, and slight graces in the S, at 8.20. Traces of an arch in the SW., from SE, to NW., reaching an altitude of about 18°, with a faint trace in the NNW., could be seen at 9.17. There was a magnetic disturbance from 3 to 9 a.m., reaching its maximum about 6 a.m.

March 15, 1883, 1.15 a, m, to 8.17 a, m.—There were traces of a faint arch in the ESE, while the twilight was still bright, coming up from near the herizon to α Boötis. The traces continued till 3.15 to 3.29, when there were bands of pale light from Pegasus through Cygnus, Lyra and Her-

NW., reaching d the zenith. c rows rapidly t to the clouds mi-corona the longest about om Leo in the 5 to 2.20, with 0 to 1). At 3 clouds in the rona E. of the to 3.20 there et (brightness e eastern edge. th the western us, Cassioneja edge. At 4.15 ls the horizon. iess 1 to 2) ran rightness 0 to the SW. SE., while the continued till yra and Herenies. At 4.20 there was a brighter arch (brightness 1 to 2) from the E. to N. through Hercules, Draco, Cepheus, Cassiopeia and Andromeda, with traces in Perseus, Aries, Corona Borealis, Ursa Major and Lynx. At 5.15 to 5.20 a broad band, waving slowly, ran from Auriga through Camelopardalis, Ursa Minor, Cassiopeia, Cepheus, Lacerta, Cygnus, Lyra and Hercules (brightness 1 to 2). At 6.17 there was a broad curtain (brightness 2 to 3) from Sagitta in the E. through Cygnus and Cassiopeia, with streamers centering towards the zenith, and a broad band from the northern extremity of the curtain to Ursa Major, with a slight vibration. At 7.15 to 7.20 a quiet band (brightness 1) ran from Leo through Coma Berenices and Boötes. The last aurora seen was a quiet arch (brightness 0 to 1) at 8.17 in the SW., from SE. to NW., reaching an altitude of about 5.50. There was a magnetic disturbance, affecting almost solely the horizontal force, between 5 and 6 a. m., reaching its maximum about 5.30.

March 16, 1883, 1 a. m. to 9.17 a. m.—At 1 a. m. there was an arch in the NE. (brightness 0 to 1) with one end near the horizon ESE, and the other in the twilight NNW., running just above  $\alpha$  Boötis, Corona Borealis and Lyra (\(\beta\)). At 1.15 this was rising rapidly and soon formed a narrow zone across the zenith again narrowing into a sinuous band (brightness 1) through Leo (a), Lynx, Camelopardalis, Cassiopeia and Andromeda. At 2 a. m. there was a broad zone with its starting points ESE, in Virgo and NNW, in Andromeda, extending in breadth from B Tauri in the SW., to n Ursa Majoris in the NE. The western band was the brightest reaching brightness 2, while the rest was pale and hazy (brightness 0 to 1). At 2.15 to 2.20 the ESE, starting point had spun out over about 20° in azimuth, forming a broad patch of very sinuous and, as it were, cardled streamers, while the eastern edge passed through Boötes, Corona Borealis, Hercules, Lyra  $(\beta)$  and (vgnus  $(\varepsilon)$ ). The whole zone was rather broken and not so bright (brightness 1 to 2). At 3 a, m, it had all faded to traces except the easternmost band, which ran through Hercules, & Lyra and ε Cygni, and was still paler at 3.15 to 3.20. At 4 a, ια, there was no aurora, but at 4.40 faint traces appeared in the NW., developing into a very transitory band across the zenith from NW, to SE. No more was seen till 9.17 a. m. when there were faint traces in the NW. The needles were somewhat agitated at the time of the aurora without any larger disturbance.

March 17, 1883, 3.15 a. m. to 9.20 a. m.—At 3.15 to 3.20 there was a faint, arched streak from hear the horizon ESE, in Virgo up through α Corona Borealis. This soon rose and formed a zone, which from 4 to 4.20 had a brightness 1 to 2, starting ESE, in Virgo, and NNW, in Andromeda, occapying Boötes, Canes Venatici, Ursa Major, Cameleopardalis, Auriga and Perseus. It was very simuous in the ESE, shifting and changing form and brightness, and rather yellow in color, At 5.15 to 5.20 it had faded to a band (brightness 0 to 1) from Orion through Gemini, Lynx, Ursa Major, Canes Venatici and Boötes. At 6.15 to 6.20 a quiet zone (brightness 1) crossed the zenith from WNW, to ESE, from Taurus through Auriga, Gemini, Lynx, Camelopardalis, Ursa Minor, Draco and Hercules. There were traces only at 7.15 to 7.20 a little south of the zenith. No more was seen till 9.20 when there were traces of an arch from SE, to NW, through Corona Borealis, Ursa Major, Lynx and Auriga. The magnets were unusually quiet all night.

March 18, 1883, 4.40 a. m. to 9.17 a. m.—At 4.40 a. m. (11.30 p. m. local) a very faint, narrow band stretched across the zenith from ESE. to NW., through Ursa Major, Camelopardalis, Auriga, and Perseus indistinct towards the horizon. At 5 to 5.20 there was a rather indistinct short band in the ENE, from Hercules to Lyra. At 7 to 7.20 a slowly waving band (brightness 0 to 1) ran from Leo through Coma Berenices, Boötes, and Serpens. At 8 to 8.20 a band of streamers waving slowly like a curtain from E. to W. ran from Perseus through Cassiopeia, Andromeda, Lacerta, and Cygmus, and two quiet bands nearly parallel extended from Aquila through Hercules, Corona Borealis, Boötes, Canes Venatici, Ursa Major, and Leo (brightness of all 1 to 2). At 9.17 there were traces in the W. The magnets were slightly disturbed from 8 to 9 a. m.

March 19, 1883, 4.40 a, m. to 6.20 a, m.—At 4.40 a pale band (brightness 0 to 1) could be seen crossing the zenith with its extremities some distance from the horizon ESE, and NW., passing through Boötes, Canes Venatici, Ursa Major, Camelopardalis, and Perseus. At 5 to 5.20 a similar band passed west of the zenith from Serpens through Boötes, Coma Berenices, and Leo. At 6 to 6.20 a band of streamers in rapid vibration (brightness 1) ran from Orion through Taurus, Perseus, Andromeda, Cassiopeia, Lacerta, and Cygnus. The needles were slightly agitated at the time of the aurora

March 20, 1883, 4.40 a. m. to ———.—At 4.40 a. m. a faint streak was observed in the ESE. coming up from Virgo through Boötes towards the zenith. This soon faded and no more was observed. Clouds, however, interfered with observation later in the night. The magnets were very quiet.

March 21, 1883, 1.15 a. m. to 9.17 a. m.-The twilight was still very bright at 1.15 (8 p. m. local) showing only the larger stars, when bright, shifting streamers began to appear 80 or 100 above the horizon ESE,, then shooting up as a band through Leo and Taurus, then forming several broad sinuous bands in Leo, which rose to the zenith and formed an elongated corona rendered indistinct by the twilight. At 2 a.m. there was a sinuous band (brightness 1 to 2) in the ESE,, running up from Virgo into Boötes and Corona Borealis, and a broad hazy zone across the zenith from the twilight in the NNW. to the moonlight in the ESE., occupying Andromeda, Cassiopeia, Perseus, Auriga, Camelopardalis, Ursa Minor, Ursa Major, and Leo. At 2.15 to 2.20 the zone was in essentially the same position, but shifting and changing from a zone to a twisted band and back again, and moving slowly westward. At 3 a. m. an area of curtains (brightness 2) rapidly developed from the NW., consisting of three or four shifting rows from Andromeda to Hydra and from near the SW, horizon to Auriga, slightly tinged with the usual colors. At 3.15 to 3.20 there was a band of curtains from Libra through Hercules,  $\alpha$  Lyrae, and  $\alpha$  Cygni, waving from E. to N. and developing a large patch in Lyra and a few bands in the place of zone at 2 a. m., which quickly developed a small faint corona and all rapidly faded. At 4 a. m. there was a similar band of curtains in the NE., partly obscured by clouds. At 4.15 to 4.20 there appeared faint bands and streamers in the N. and NE, mixed with patches of cloud. Clouds interfered with observation at the next two hours, but it had cleared at 7.15 to 7.20, and showed a quiet band (brightness & to 1) from Aquila through Pegasus, Andromeda, and Perseus from E. to NNW. At 9.17 there was a corona of long slender rays centering towards the zenith, waving slightly. The needles began to be agitated at the first sign of the aurora, and the disturbance continued all night, reaching its maximum at 3 p. m.

March 23, 1883, 1 a.m. to 8.20 a.m.—At 1 a.m., while the daylight was still very bright, so that only the largest stars were visible, there was a white, sinuous, shifting streak in the E. near Arcturus. At 1.15 a.m. there was one arched band in the E. through Arcturus and Virgo, and a twisted, shifting band across the zenith from SE. to NW., soon fading, and extensive patches developing in the E. At 2 a.m. a rather narrow, shifting zone, waving slowly, crossed the zenith from the ESE, in Virgo to NW. in Andromeda through Boötes, Canes Venatici, Ursa Major, Ursa Minor, Cepheus, Cassiopeia, Perseus, and Andromeda, and two arched sinuous bands in the NE., the upper through Corona Borealis, Hercules,  $\alpha$  Lyra, and  $\alpha$  Cygni, and the lower near the horizon. At 2.15 to 2.20 the zone had shifted W. nearly to  $\alpha$  Auriga, fading gradually, while a new zone developed the former place and bands in the E. shifted. Clouds interfered with the next three observations, and, though the sky then cleared, no more aurora was seen till 8.15 to 8.20, when a yellowish band (brightness 1), waving slowly, ran through Leo, Leo Minor, Ursa Major, Canes Venatici, Draco, and Cygnus, sending up a few rapidly vibrating streamers in Cygnus. The magnets were disturbed from 7 a, m. to 2 p. m., the maximum disturbance being at 8 a, m.

March 24, 1883, 1.45 α, m. to 3.15 α, m.—The twilight was still bright at 1.45, but a well-defined arch (brightness 1) was observed running through Boötes (just above α), Corona Borealis, Hercules, Draco, and α Cygni, and rising rapidly. At 2 a, m. a broad yellowish band (brightness 1 to 2), fringed on the upper edge, with ill-defined streamers, lay in the NE., passing through Canes Venatici, the tail of the Great Bear, Draco, and Cygnus to the twilight in the NW. This had risen at 2.15 a, m. to form a narrow zone (brightness 1) from the ESE, to NW, through Canes Venatici, Ursa Major, Ursa Minor, Draco, Cepheus and Cassiogen to Andromeda. Three or four ill-defined rolling curtains developed quickly from the E, towards the N., with rapid, quivering motion propagated in the same direction through Boötes, Corona Borealis, Hercules and Lyra, reaching a brightness of 2 to 3 in Boötes in the E, with a bright display of green, yellow, and rose in the usual order, quickly quieting down and growing paler, while the zone widened in both directions to about twice its usual width and growing hazy, and then developing a waving motion on the western edge. At the next observation the clouds already so obscured the aurora that traces

in the ESE, no more was nagnets were

1.15 (8 p. m. ear 80 or 100 then forming gated corona ess 1 to 2) in y zone across Andromeda, t 2.15 to 2.20 to a twisted brightness 2) ndromeda to ors. At 3.15 ygni, waving f zone at 2 a. . there was a ere appeared terfered with a quiet band o NNW. At lightly. The ued all night,

well-defined lis, Hercules, tness 1 to 2), rough Canes 7. This had rough Canes Phree or four id, quivering es and Lyra, low, and rose in both direcing motion on a that traces of an arch were alone visible in the E. The clouds prevented further observation entirely. The needles were quiet, with a high horizontal force.

March 26, 1883, 1.15 a. m. to 5.29 a. m.—It was still broad daylight at 1.15, but a perturbation of the magnets indicated an aurora, which was seen on leaving the observatory as a pale, shifting, simuous band from rear the horizon ESE, and passing up about 20° E, of the zenith. At 2 a. m. a narrow zone (brightness 1 to 2) ran from the ESE, in Virgo to the twilight in the NW., through the sickle of Leo, Gemini, Taurus, and Aries. At 2.15 to 2.20 this had spread eastward to within about 10° of the eastern horizon, broken up into sinuous bands and curtains, brightest in the E. and N., whirling curtains in the E. and a vertical loop in N., quickly developing into an arched hand and again bearing a loop with rapid motion, both waving and vibrating, and showing rather bright colors—green, yellow, and rose—the green especially appearing against the twilight. At 3 a. m. there was a broad zone of ter bands (brightness 2) with its starting points in Virgo ESE., and NW, in Aries, extending in breadth from Procyon to Polaris. It was in essentially the same place at 3.15 to 3.20, but there were more bands, shifting, broken, and hazy, some approaching the form of curtains, growing paler and then brighter again, especially in the ESE., where the bands were very sinuous. Clouds interfered with observation the next bour, but traces were seen in the W. At 5.15 to 5.20 a band (brightness 1) ran from Serpens through Boötes, Coma Berenices, Leo, Cancer, Gemini, and Orion, with a few quiet streamers in Serpens and Boötes. The magnets were disturbed all night.

March 27, 1883, 2.15 a. m. to 6.20 a. m.—The sky was covered with hazy clouds at 2 a. m., but these were sufficiently thin at 2.15 to 2.20 to show traces of a narrow band across the zenith from the NW, to SE. At 3 a. m. there were three or four bands, obscured by the hazy clouds lying low in the SW., passing through Virgo, the lower part of Leo, into Canis Minor and Taurus (brightness 1). The position of these bands was practically unchanged at 3.15 to 3.20, but the upper band was broadened and fringed out into ill-defined streamers, while the lowest was narrow and bright. All were shifting and changing in brightness (brightness 1 to 2) and bright streamers developed in the SE. At 3.15 there was a large, complete, and quiet regular corona (brightness 1), of about 40° radius, centering in Ursa Major, near the zenith, with a broad band on the western edge and twisted shifting streaks near the center. This had become a broad zone at 4 a, m., partly obscured by the clouds (brightness 1 to 2) from the NW, to SE., extending in breadth from the lower edge of Draco to Procyon, and at 4.15 to 4.20 had again become a corona, but more incomplete and elongated, running down towards the horizon in the E., with a bright (2 to 3) and quiet regular arch in the W., with an attitude of about 25°. All shifted rather rapidly, with a loop in the NW. (altitude about 35°), increasing in brightness 2 to 3, and finally all settling into a broad zone. At 5 to 5.20 quiet bands (brightness 0 to 1) were visible through the dense haze running through Coma Berenices, Canes Venatici, Ursa Major, Leo, Lynx, Cancer, and Gemini. At 6.15 to 6.20 there was a bright coroua (brightness 2 to 3) centering in Ursa Major. The streamers were very short in the N., not reaching the zenith. The edge of the corona was in Serpens, Boötes, Orion, Gemini, Auriga, Lyax, Hydra, and Leo, all in rapid motion from E. to W. Clouds then interfered more or less with observation, rendering it impossible to determine the end of the aurora. A violent magnetic disturbance commenced about 3 a. m. and still continues.

March 28, 1883, 2 a. m. to 6.20 a. m.—At 2 a. m., partly obscured by the clouds, there were bands coming up from the ESE. At 2.15 to 2.20 there was a bright arched band (brightness 2 to 3) in the SW. from the ESE., in Crater through Hydra  $(\alpha)$ , Monoceros and Orion  $(\gamma)$ , narrow and curling down in the NW. It was bright yellow, shading into rose on the lower edge, flickering slightly, and then developing rapid motion in the NW and rising at the same time to  $\alpha$  Canis Minor is, broadening at the same time, while a second and then a third bard above this and only about half as long developed from the ESE., and then growing paler and sinking. At 3 a. m. the whole sky was covered with broad hazy bands and curved patches running NW, and SE. At 3.15 to 3.20 there was a loop in the N. and NNE, from Aries, through Andromeda into Cygnus, shifting and rising, while a broad hazy band developed from the NW. to SE, across the zenith, and with the loop formed a semi-corona E, of the zenith, much elongated, and then becoming a band of streamers (brightness 2 to 3) from Aries through Andromeda, Cassiopeia, Cepheus, Draco, and Corona Borealis and then curving back through Lyra, vibrating rapidly from E, to N., rising

towards the zenith, and splitting. At 4 a. m. there was a broad zone from ESE, to NW, (brightness I) made up of coronal streamers east of the zenith, not reaching lower than Cepheus, while all the western sky was covered. At 4.15 to 4.20 there was a zone of four main bands (brightness I to 2) from the SW, horizon nearly to the zenith, with the same starting point, but curving back in the E, through Aquila. The upper band was edged with short streamers, and long streamers began to develop in the E, At 5 to 5.20 the whole sky was covered with quiet bands (brightness 0 to 1) running WNW, to SE. At 6.15 to 6.20 there were traces of a great corona covering the sky. No more was observed. Yesterday's magnetic disturbance continued.

March 29, 1883, 3.45 a. m. to 8.15 a. m.—The aurora was only observed at intervals of fair weather during the night. At 3.45 broad bands in the W. suddenly shot up to the zenith, with rapid vibration and play of colors, and formed a corona, apparently covering the whole sky. At 4 a. m. the corona still persisted, and surrounded by belts of curtains covered nearly all the sky (brightness 1 to 2). It was partly obscured by clouds and haze, but appeared to be in motion, suffting and waving with rapid vibration in the NE., and bright yellow patches showing through the clouds. It had partly faded at 4.15 to 4.20, and was much obscured by haze and clouds. Traces only were seen at the next hour. The sky was clear enough at 7.15 to 7.20 to show quiet bands (brightness 1), forming a zone, occupying Orion, Taurus, Gemini, Perseus, Andromeda, Lynx, Ursa Major, Cassiopeia, Cepheus, Boötes, Corona Borealis, Lacerta, Cygnus and Lyra, Traces were visible at 8.15. The needles were quiet up to 4 a. m., when a violent disturbance commenced and still continues.

March 30, 1883, 7.15 a. m. to 7.20 a. m.—The sky, which had been cloudy all night, cleaned about 7.15 a. m., displaying a slowly waving band from Gemini through Lynx, Ursa Major, Canes Venatici and Boötes (brightness 0 to 1). The needles were somewhat disturbed from 4 a. m. to 1 p. m.

April 2, 1883, 2.15 a. m. to 7.20 a. m.—There were traces of a band in the ESE, at 2.15, which at 3 a. m. had developed into a broad hazy zone from the ESE, in Virgo, fading in the twilight in the NNW, reaching in breadth from θ Ursa Majoris to β and β Draconis. This had condensed at 3.15 to 3.20 to a broad based in the SW, through Virgo, Hydra, Leo, Gemini, Cancer, Canis Mine γ the upper part of Orion and Taurus, and beginning to shift and break (brightness 1). At 4 a. m. there was a broad, ill-defined, sinuous band in the NE, from near α Serpentis, through Heredies, Lyra and Cygnus, into Pegasus, and a hazy band starting from the same place, running through Boötes, Canes Venatici, Ursa Major, Lynx, Auriga and Perseus (brightness 0 to 1), and all had faded to traces at 4.15 to 4.20 except the band in the E, and this even had become traces at 5 to 5.20. At 6.15 to 6.20 a belt of slowly waving bands, with a few patches of streamers in Aquila, ran from Taurus, through Auriga, Perseus, Andromeda and Cassiopeia, to Cygnus (brightness 1). At 7.15 to 7.20 there was a short band from Ursa Major to Boötes in slow motion from W, to E, and a rather motionless band from Perseus and Cassiopeia to Cepheus (brightness 0 to 1). A magnetic disturbance commenced at 3 a. m., and was not over when the aurora ended, reaching its maximum at 12 m.

April 3, 1883, 1.45 a. m. to 7.20 a. m.—A slight agitation of the needles indicated aurora, which appeared at 1.45 as very faint, evanescent white streamers in the ESF., while the daylight was still bright. There was none to be seen at 2 a. m., but at 2.15 there were traces of bands high in the SW. These had developed at 3 a. m. into a narrow hazy zone W. of the zenith from ESE., in Virgo, to the twilight NW., occupying Leo, Cancer, Gemini, Auriga and Taurus, which had risen at 3.15 to 3.20 to Ursa Major, while what had been simous bands in Scrpentis in the E. began to develop into curtains (brightness 1), with waving hadion. The whole sky was covered at 4 a. m. with a sort of elongated corona, approaching the horizon in the ESE, and NW., and extending from below Procyon, in the SW., to α Cygni and α Lyrae in the NE. (brightness 0 to 1). It was made up of rather sparsely scattered bands, rows, and curtains, which lattice were best devel oped and brightest in the S, and SE, with some motion. It was broken and paler, reaching nearly to the SW, horizon, about 10° higher in the NE, where it consisted of long streamers. This was attended with considerable magnetic disturbance. At 5 to 5.20 there was a corona, curling in Ursa Major, with long streamers, reaching to the horizon in the E, and W. They were not so bright in the S,, and only reached the zenich in the N. The whole was quiet (brightness 0 to 1),

This was a, curling in were not so ness 0 to 1), and continued unchanged at 6.15 to 6.20. At 7.15 to 7.20 there were only left traces of long streamers in the S., all running to Ursa Major. The magnetic disturbance still continued at 9 p. m.

April 4, 1883, 1.45 a. m. to 7.20 a. m.—At 1.45 the daylight was still bright, and an exceedingly faint band appeared in the ESE, extending towards the NW, about 10° west of the zenith. None was to be seen at 2 a. m., but at 2.15 to 2.20 there were traces in the ESE, gradually developing into very pale shifting curtains across the SW, beginning to wave rather rapidly in the S. At 3 a. m. there was a broad shifting lazy zone across the zenith from ESE, in Virgo to the NW, with the western edge in Hydra, Canis Minor and Orion, and its eastern in Boötes, Ursa Major, Draco, Cepheus, Cassiopeia and Perseus (brightness 0 to 1). This had faded to traces at 3.15 to 3.20, except some brighter bands in the E, through Serpens, Aquila, and the lower part of Cygnus, quickly rising to α Lyrae and instantly fading. At 4 a. m. traces of the zone were to be seen and a patch of ill-defined curtains (brightness 1 to 2) in Cygnus and Andromeda, NNE., with a bright long streamer or two. All had faded to traces at 4.15 to 4.20, but curtains were beginning to develop in the NNW. At 5.15 to 5.20 there was a band of slowly vibrating streamers (brightness 1) from Taurus through Auriga, Perseus, Cassiopeia and Cepheus. At 6.15 to 6.20 there was a quiet band (brightness 0 to 1) through Gemini, Lynx, Ursa Major and Boötes. Traces alone remained at 7.15 to 7.20. The magnetic disturbance continued all night.

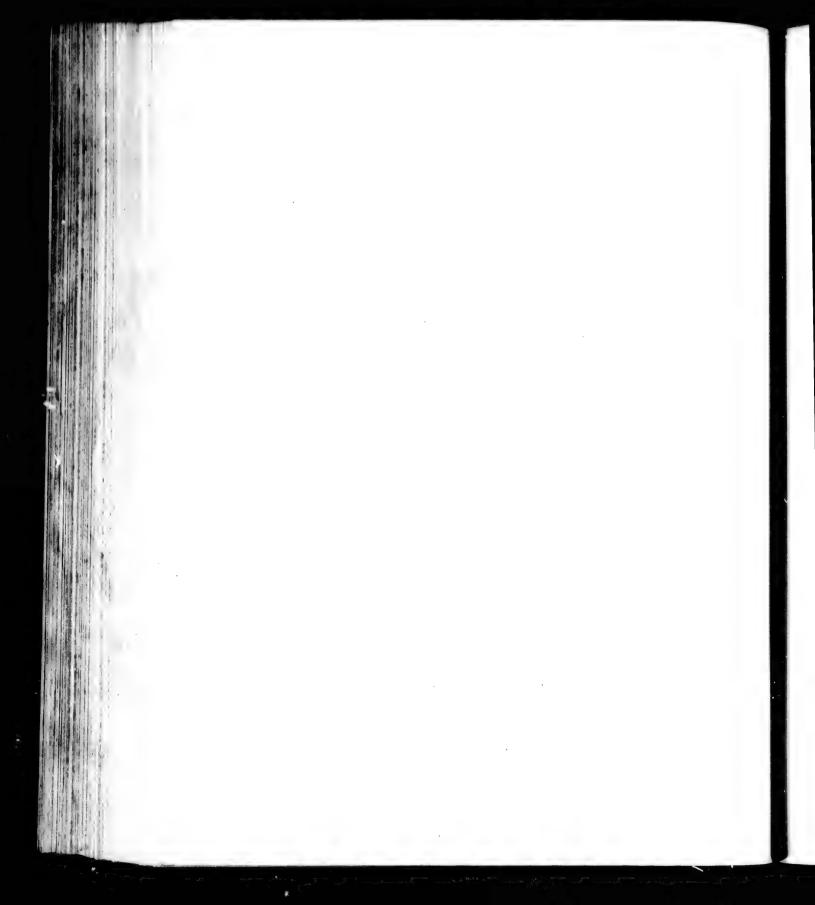

April —, 1883, 4.15 a. m. to — — — The sky was covered by clouds all night, but at 4.15 to 4.20, when the magnets were very much disturbed, auroral light appeared in the NE. showing strongly through the clouds, and quickly rose as a band reross the zenith and disappeared in the W., while fresh patches of light developed in the E. The magnetic disturbance continued all night.

April 8, 1883, 3.45 a. m. to 6.20 a. m.—Sinuous traces appeared in the ESE, at 3.45 and had developed at 4 a. m. into defiaite pale sinuous bands in the E. coming up through Aquila into Lyra and Cygnus. At 4.15 to 4.20 these had developed into a broad belt of waving sinuous bands (brightness 1 to 2) in slow motion extending from Aquila near α through Lyra, Cygnus, Cassiopeia and Perseus, and gradually broadening and shifting and rising. These had faded to quiet bands (brightness 0 to 1) at 5 to 5.20, crossing high in the sky through Auriga, Gemini, Lynx, Camelopardalis, Ursa Major, Ursa Minor, Draco, Boötes and Hercules. Traces were still visible in the 8, at 6 to 6.20.

April 9, 1883, 3.45 a. m. to 6.20 a. m.—A very faint band crossed the Ph through Boötes and Ursa Major, running SE, and NW, at 3.45 a. m. This had become sinuous and shifting at 4 a. m. and extended on through Cephens and Persens, with shifting sinuous bands on either side, one in Draco and the other in Auriga and Gemini. All had faded to traces at 4.15 to 4.20. At 5 to 5.20 a faint luminous band ran from Serpens through Boötes to Coma Berenices (brightness 0 to 1). Traces only were to be seen at 6 to 6.20. There was magnetic disturbance chiefly affecting the horizontal force at about 8 a. m.

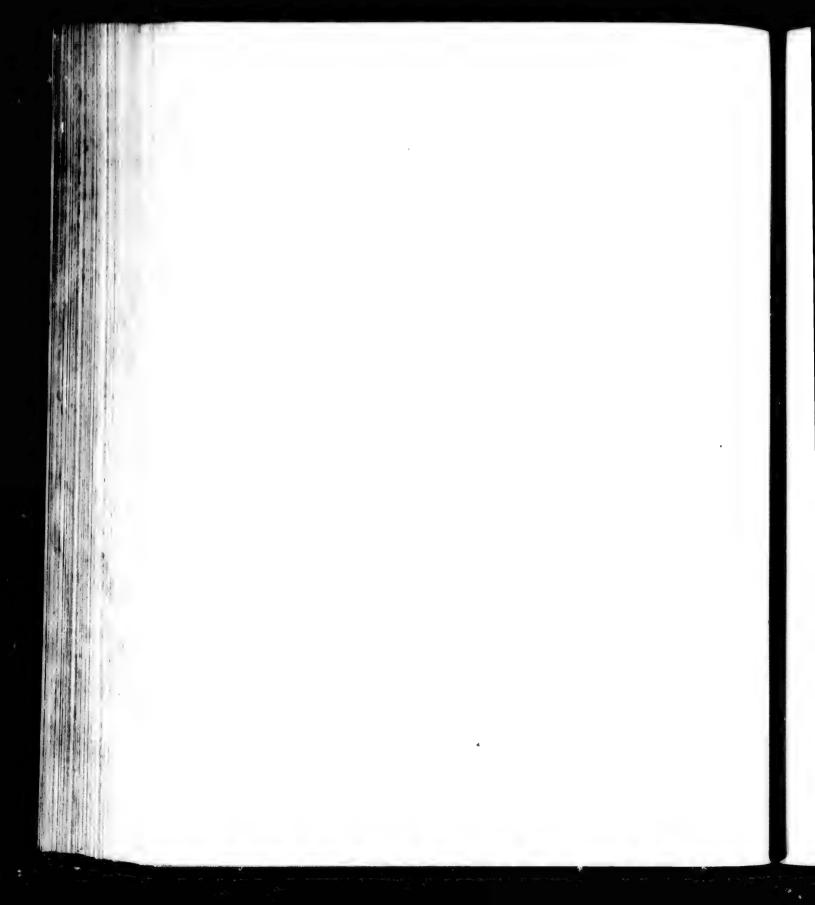

April 13, 3.45 a. m. to 5.20 a. m.—At 3.45 the twilight was quite bright and the stars obscured by haze. A faint arched yellow band lay in the SW. from near the horizon ESE to the light in the NW, reaching an altitude of about 40°. At 4 a. m. there were barely perceptible traces in the SW., but at 4.15, as indicated by the agitation of the needles, there was an extensive aurora in rapid waving and vibrating motion in the form of a zone about 30 or 40 degrees broad, and composed mostly of curtains and coronal streamers, crossing the zenith from ESE, to NW. The usual color appeared with the yellow very prominent (brightness 2 to 3) and the whole moved quickly toward the magnetic N. The stars were only faintly visible. When the north magnetic edge had reached a Lyrae the rest had faded, and all was soon reduced to sinuous traces occasionally brightening up again, but all was nearly faded at 4.20. These developed into a narrow band again at 4.45, but at 5 to 5.20 there was only a pale, quiet band (brightness 0 to 1) through Persens, Andromeda, Cassiopeia, Lacerta and Cygnus. The needles continued more or less agitated till 2 p. m., being considerably disturbed at 1 p. m.

# PART VI.

TERRESTRIAL MAGNETISM.

## TERRESTRIAL MAGNETISM.

The magnetic records were placed in the hands of the United States Coast and Geodetic Survey for computation and discussion.

The following report is presented:

ACCOUNT AND RECORD OF THE MAGNETIC OBSERVATIONS WITH PARTIAL RESULTS DEDUCED BY C. A. SCHOTT, ASSISTANT, COAST AND GEODETIC SURVEY.

Computing Division, Coast and Geodetic Survey Office,

May 6, 1884.

J. E. HILGARD.

Superintendent Coast and Geodetic Survey:

DEAR SIR: Towards the end of March, 1881, Mr. Carlile P. Patterson, then Superintendent of the United States Coast and Geodetic Survey, was invited to aid and co-operate in the researches proposed by the International Polar Commission, which held its second session at Bern, Switzerland, in August, 1880, H. Wild, president. General W. B. Hazen, Chief of the United States Signal Corps, United States Army, having notified the Commission that the United States would take part in the undertaking, caused two expeditions to be fitted out, one to proceed to Point Barrow, Alaska, the other to Lady Franklin Bay, Grinnell Land. The Coast and Geodetic Survey was to co operate in the magnetic work which these parties were to execute by furnishing such magnetic and other instruments as were then available and by instructing three or four observers of the Signal Corps in their use; besides bearing a part of the expense of the first-named expedition, the second expedition having been provided for by special appropriation of Congress.

#### PART I.—INTRODUCTION.

It was not until near the close of April that these preliminary arrangements were concluded: and it was well understood, in consequence of the want of suitable magnetic instruments, and in particular of differential instruments, and owing to the fact that no trained scientific observers were at the time available, that the Coast and Geodetic Survey could not then follow the minute instructions which had been prepared for the guidance of the various expeditions which were to take part in the work of the Commission. In the words of the Superintendent, we were simply to do for terrestrial magnetism the best that was possible at the time. For the first year at Point Barrow, and during the entire absence of the other expedition, the assistance of the survey was more incidental than fully co-operative; but this condition was considerably improved in the second year at Point Barrow, when we were able to send a set of differential instruments with a newly instructed observer. In the summer of 1883 a special observer was sent in charge of pendulum work and particularly to verify the magnetic work, as well as to redetermine the geographical position and the true meridian or azimuth; but unfortunately he was unable to accomplish anything in consequence of the continued rain, fog, or cloudiness of the sky during the few days he could stay at the place, the state of the ice and the damaged condition of the vessel demanding a speedy embarkation of the whole party.

That under these circumstances the magnetic work should fall somewhat short of the accuracy which the committee had desired it should possess is not surprising; indeed, the Polar Conference

found afterwards that so far as the first year's magnetic work was concerned it appeared to have been undertaken rather prematurely, inasmuch as it could not be supposed that differential instruments of a particular description were ready at hand, nor was there sufficient time to procure them. Disclaiming, therefore, such close co-operation as would have been desirable, but which was impossible under the circumstances, the records and results herewith presented are the outcome of faithful labor and are believed to be an acceptable contribution to our knowledge of magnetism in high latitudes, and it is thought that in the second year, at least, these records will prove to be a valuable part of the material accumulated by the several expeditions.

Later on, in full co-operation with the work undertaken by the International Polar Commission, the Coast and Geodetic Survey established at Los Angeles, Cal., a magnetic observatory and equipped it with a set of Adie's self-recording magnetometers of the Kew pattern. In the spring of 1882 the adobe building had been constructed by Assistant J. S. Lawson, and in July following the instruments were mounted and the photographic process was arranged by Mr. W. Suess, mechanician Coast and Geodetic Survey. The observatory was then permanently-turned over to the charge of Mr. Marcus Baker, Coast and Geodetic Survey, under whose direction the absolute and differential measurements have been made uninterruptedly from about the end of September, 1882, to the present time, and it is the intention to continue the work for some years.

In May, 1881, Mr. J. B. Baylor, and in June following, Mr. M. Baker, of the Coast and Geodetic Survey, were detailed to instruct at Washington Sergeants E. Israel, J. Cassidy, J. Murdoch, and M. Smith, Signal Corps, U. S. Army, in the use of the sextant and the alt-azimuth for the determination of time, latitude, longitude, and azimuth, and in the requisite computations; they were likewise instructed in the use of those magnetic instruments which they were to take with them, Mr. A. C. Dark was instructed at San Francisco in astronomical observations by Subassistant J. F. Pratt, Coast and Geodetic Survey. With the exception of Sergeant Israel, who proceeded to Lady Pranklin Bay, the above named observers formed part of the personnel of the Point Barrow party. These observers made the best use of the short time available for their instruction.

In May, 1882, J. Pahnarts and Sergeant J. E. Maxfield, Signal Corps, U. S. A., received instructions from Mr. Baker in the use of the sextant and the theodolite, and in June they practiced under Assistant Eimbeck, Coast and Geodetic Survey, with the Brooke differential instruments which left the office for Point Barrow June 14, 1882.

The following instructions to the parties were drawn up (June 9, 1881) by the writer under direction of Superintendent C. P. Patterson:

4 Instructions and notes for the guidance of the observers to be stationed at Point Barrow, Alaska, and at Lady Franklin Bay, north of Smith Sound, Arctic Ocean.

"As soon as the quarters of the expedition have been fixed upon a magnetic house will be erected, in which the regular magnetic observations as described below will be made; other observations will be made when on boat or sledge trips.

"Instruments.—For the use of the magnetic observatory there will be provided a magnet ometer, for absolute and differential declination and for horizontal magnetic intensity, to be per manently mounted on a stone pier. In connection with this instrument a meridian or azimuth mark will be established a short distance off the observatory and visible from it through an open ing in its wall. The astronomical bearing of this mark will be carefully determined by means of an altrazimuth instrument and solar observations. In the same house, but on a separate pier, will be mounted a Kew dip-circle, and, in the case of Point Barrow, a third instrument, a bifilar magnetometer, will also be permanently mounted on its pier. At Point Barrow the magnetometer or unifilary and the bifilar instruments will be mounted in the magnetic meridian and at a distance apart of not less than twelve feet, and the dip circle will be mounted equidistant from these instruments, forming an equilateral triangle. At Lady Franklin Bay the two instruments will be mounted in the plane of the magnetic prime vertical and not less than 12 feet apart. No iron is to be used in the construction of these buildings and they should not be nearer than fifty yards to any other building or double that distance to any large mass of iron. Special reading lamps (of copper must be provided for use with the instruments, and they must be tested to make sure that

cared to have cential instruprocure them, th was imposcome of faithctism in high to be a valua-

r Commission, servatory and In the spring fully following Ir. W. Suess, urned over to a the absolute of September,

r, Alaska, and

house will be tother obser-

ed a magnet ity, to be per mor azimuth ough an open by means of rate pier, will a bifilar magnetometer for at a distance these instrunents will be No iron is to fifty yards to ling lamps (of ake sure that they do not affect the position of the magnets. The use of candles stuck in wooden blocks is preferable to lamps.

· When on boat or sledge journeys the party will carry a chronometer, a small alf-azimuth instrument with circles of about three inches diameter (as constructed by Fauth & Co., of Washington, or by Casella, of London), provided with a magnetic needle or compass mounted over its vertical axis, and a dip circle.

· Observations at the permanent station,—Hourly observations will be made for declination and diamal variation with the magnetometer on three consecutive days about the middle of each month; besides these observations, extending over seventy-two hours, there will be made at any convenient intermediate time each day (of the three) one set of deflections, followed immediately by a set of oscillations for the determination of the horizontal intensity. At Point Barrow the bifflar will be read immediately after the unifilar. There will also be made at any intermediate time each day (of the three) a set of dip observations. In connection with the declination, the mark will be read once each day (unless the instrument should accidentally be disturbed), but it suffices to determine the magnetic axis of the declination magnet on one of three days. The instrumental constants of the magnetomater will be determined before leaving Washington, and the observer will use the Coast and Goodetic magnetic blank forms for their records, or, in case no special forms are provided, they will use small (octavo) note-books; they will also compute, as soon as the observations are completed each month, the magnetic mean declination, diurnal range, and turning hours; also the horizontal force in absolute measure (English units) and the dip, tabulating the results for each day.

Extra observations on other than the three days about the middle of each month will be made during all occurrences of auroral displays, but as they are likely to be very numerous at Point Barrow observers there may confine their extra observations to the more conspicuous displays only. On these occasions the declinometer (and the bifilar) at Point Barrow will be read every 10 minutes or oftener, or less often, as the state of the needle may appear to demand, the object being to ascertain the relation and establish a connection between the appearance of the annorm and the motion of the magnetic needle.

"When landing on a boat journey or during a sledge journey, at suitable stations (not less than 10 or 15 miles apart), the time, latitude, and azimuth will be determined by the alt-azimuth instrument and the declination by the same instrument (the hour and minutes of the observation is to be noted in order that the diurnal variation may be allowed for); the dip will also be observed, and in case time is pressing, reversal of circle, reversal of face of needle, and reversal of polarity of needle may be dispensed with, but the needed corrections to the result from the single position of the instrument or needle must be ascertained at the permanent station. Observations of deflections with magnetic needle and with weights will be made with the dip circle as arranged for relative and absolute total force, the data for the latter to be supplied at the permanent station.

"It is highly desirable, especially in the case of the Lady Franklia Bay party, that all stations within reach and formerly occupied by other parties for magnetic purposes, be revisited in order to farnish material from which to deduce the secular change during the interval; besides all opportunities should be taken when landing on the way up, to secure observations for declination, dip, and intensity; the latter, best by oscillations of the intensity magnet. The winter quarters of the late English expedition should be connected magnetically with the present quarters.

"All magnetic observations will be made on Göttingen time, as provided for by the Hamburg Conserves."

"All magnetic work will be kept strictly in conformity with 'Notes on measurements of tenestrial magnetism,' United States Coast Survey, Washington, D. C., 1877,† and other records in cot; ection therewith should be equally clear and complete, and all computations should be made by the observer in separate books. Duplicates of all records will be made, compared with the original, and the latter returned annually,‡ if practicable, to the Superintendent of the Coast and Geodetic Survey, Washington, D. C. The observers should also provide themselves with copies

" This sentence I find added to original report.--[Sch.]

A new edition, the third, has since appeared in Appendix No. 8, Coast and Geodetic Survey Report for 1881. It was then supposed that the parties would remain out for three years.

of the Admiralty Manual of Scientific Inquiry, the Arctic Manual and Instructions, 1875, and Aurorae, their character and spectra, by J. R. Capron, 1880. Also, with Terrestrial and Cosmical Magnetism, by E. Walker, 1866, and any other work they may require for their information."

Besides the above paper, which is printed (pp. 12 to 14) in "Instructions No. 72, War Department, Office of the Chief Signal Officer, Washington, D. C., June 17, 1881," the parties received additional instructions headed (2) Obligatory observations in the domain of terrestrial magnetism, and (3) Elective observations—contained in the same order. Among these optional observations are mentioned observations of tides and of earth currents; for both of these phenomena returns were made.

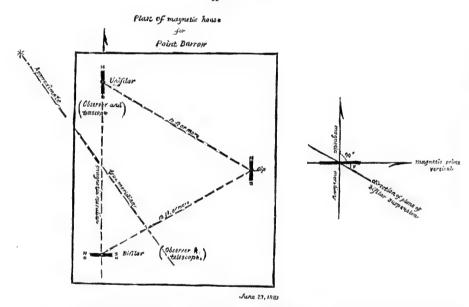

The Point Barrow party was also provided with a plan of the magnetic house, and received the following note respecting the adjustment of the bifilar magetometer, which had been hastily constructed from some remains of an older instrument:

"The portable bifilar magnetometer.—This instrument was reconstructed from such parts as could be found from an old instrument. A collimator magnet was provided, also a new bifilar suspension adjustable by means of a right and left handed screw in the place of a disk, as originally supplied; the projecting arms indicating that the instrument had been arranged for an induction inclinometer were removed.

"It is to be used differentially or for variations only of the horizontal component of the magnetic force. The instrument is to be adjusted with the axis of the collimator magnet in the magnetic prime-vertical, and the variations of the horizontal force observed by readings of the scale.

"If H= horizontal magnetic force,  $\Delta H$ = variation of the same, v= angle of twist in the bifilar suspension (usually between 40° and 70°),  $\Delta v$ = variation of this angle (expressed in parts of radius) then

$$\frac{JH}{H} = \cot v J v$$

"If  $n_0 =$  reading of the scale of any fixed part, say of the magnetic axis of the collimator, n = any reading at another time, a = value of one division of the scale in parts of radius (or angular value in minutes times .000291), then  $\Delta v = (n - n_0) a$ .

ctions, 1875, and al and Cosmical 72, War Depart. parties received trial magnetism. nal observations nomena returns

nent of the maggnet in the maggs of the scale. wist in the bifilar ssed in parts of

iformation."

"To correct for changes in the value of  $\frac{JH}{H}$  for change of temperature of magnet let  $e^{\pm i t}$ change of magnetic moment of magnet corresponding to a change of 10 Fahr, we have the corresponding to a change of 10 Fahr, tion  $q(t-t_0)$  where  $t_0 =$  normal temperature a 'opted' and t, any other temperature. The value of q may be found by a series of observations of oscillations at high and low temperatures, the magnetic net being suspended as in the unimbar magne-ometer. Putting  $k=\sigma$  cet v we have

$$\frac{dI}{dt} = 2\left(t + 2a\right) + q\left(t + t_0\right)$$

the value of "may be about ,0000, and it should be so arranged, by varying the distance of the threads, that the least integer reading of the scale should indicate about  $\frac{1}{1000}$  to  $\frac{1}{10000}$  parcef the  $^{\circ}$ 

Let so tal force. The observed variation in the hecknowal component of the magnetic force will be true only in case the magnetic moment of the suspended magnet remains unchanged during the time of observations, but as every magnet gradually loses magnetism a further correction for loss of magnetic moment is needed. This may be determined by comparing differences of values of horizontal force as determined by means of the unifilar magnetometer at certain times (and after long fatervals) with a series of corresponding readings of the differential instrument. The . Let being an old one, it seems best to examine and readjust the bifilar at the end of each year crottener in case of necessity.

. The north end of the magnet may be turned clober to the right or left of the meridian, but , will be desirable to choose that side which will make increasing horizontal force correspond to sing scale readings.

· The principal adjustments of the instrument may be summed up as follows:

"Level; su pend magnet as unifilar; focus telescope; place scale Lorizoned and admit light for distinct vision; take torsion out of suspension; and plane of detorsion in magnetic meridian; determine axis of collimator; determine scale value or value of one division is minutes or are; 🚭 ton axis and note corresponding scale reading of magnetic meridian; take off units and substitute bitlar tube; place plane of bifilar suspension in magnetic meridian, point on asis and read torsion chele; test this by turning telescope 180° in azimuth and bringing the magnet in the acversed position, north end to the south, and read torsion scale; if it reads as before, the plane of threads was truly in the magnetic meridian; repeat adjustment if necessary; turn telescope 90 trainto the magnetic prime-vertical and turn in the rance direction the torsion circle mutil the axis et a collimator appears pointed in telescope; read the torion circle, it will be the section the toridian value; compute the value of k and after the distance of thread. By the corresponding until a satisfactory value for k is found.

To determine the torsion coefficient  $\frac{h}{f}$  let a=angle through which the magnet was deflected, and z=angle through which the torsion circle had been turned; then  $\frac{h}{f}=\frac{a}{p+a}$ ; hence scale value  $a=\left(1+\frac{h}{f}\right)$  expressed in minutes of are. Increasing numbers of scale should correspond to a notion of the north end of the magnet to the cast. The scale is numbered from 20 to 80, which numbers a> to be read 200 and 800, and thus has a range of  $5^{\circ}$  on either side of the normal position. Two space scales, divided on white bristol board, about 15 centimeters long, p(s)=f additional extent of the should be made, and, in case of necessity, fastened to the ends of the reading scale. The particular cross thread of the theorem is to be kept on the 500 mark, p(s)=f reading scale. The articular cross thread of the appears to each of the instruments. The definition of the fixed and movable mirrors is in the plane of the optical that the tele cope. The instrument is blaced under a zing cover.

ow let H and  $\gamma$  vary by  $\delta H$  and  $\delta z$  and the ratio,  $\frac{\delta H}{H}$ , or the variation of the horizontal force  $\varphi$  and in parts of the force, is given by the relation

$$\frac{2H}{H}$$
 entrop

"Suppose the scale division to be 1 millimeter and the distance of the scale and minimillimeter, then  $\partial z = \frac{1}{2x}$ . Now putting for z; its equivalent a ( $a = a_0 z$ ,  $v = a_0 z$ ) and of each division of scale in terms of radius and  $a = a_0 z$  the directness of any two scale is a fact, and smaller k = a cot z, the ratio,  $\frac{\partial H}{\partial z}$  becomes k ( $n = a_0 z$ ). A second method for determining z,  $z = a_0 z$ ,  $z = a_0 z$ , as follows: Let  $m = \frac{W}{100}$ , or let it be equal to any other convenient fraction of W, and  $z = a_0 z$ .

An important addition to the Briefer instruments as instancy the stability or axity of the direction at point of the scale; the idea was taken to an the later Adic magnetograph. The circular windows of the thometers were of Franch planteglass. It wind on Petunary 11, 1881, I and that the representation is so that the excellent sufficient with the fight refraction by turning the glass critically apparent the deviation changed from a tree division on a graph of the scale

responded to a cate the new concerned of the two readings of the scale, that is, before and after the small weight was added, or for weight W and for weight W+w will correspond to above both borizontal force. To give the instrument any desired sensitiveness compute the angle of deflection <math>z corresponding to it, and set the torsion circle accordingly, then by means of the upper suspension screw, with its two sets of opposing screw-threads, the suspension threads are to be brought to that distance, which will bring the middle of the scale (50) on the vertical thread of the telescope. Using the second method a weight has to be provided corresponding to the desired sensitiveness, and the suspension threads must be regulated in order that the additional weight may produce a change of a certain number of divisions of scale when it is added and taken off.

The instrument is provided with a mechanical compensation for changes of temperature. In view of the extreme low temperatures which are likely to be experienced at Point Barrow, he cover, and under the present circumstances, it will be better to deduce the corrections for any outstanding amount, not compensated, differentially from the observations of the horizontal force themselves, than to attempt a complete mechanical compensation. The latter operates as follows:

A STATE OF THE STA

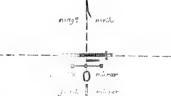

Referring to accompanying figure, suppose the temperature increases, the effective force of the magnet will diminish, the differential expansion of glass and zine (which materials form the compensation) will push the zine and in, which brings the suspension three leadings together, and thus diminishes the zine force balancing H in the same ratio that if itself diminishes. Increasing scale readings should correspond to increasing hoticistal magnetic force, or correspond to a move of the north and of the magnet toward is north. The narrow space dividing the basic

cal plane and port and susg for it), as in the case of a free declination magnet, observing that the sides which were vertical when on its bearings will now be horizontal. The moment of inertia will be the same as before. Let  $T_1$  = the time of a horizontal oscillation, then—

$${^{\hat{\sigma}} V = \frac{T_1^2}{T^2}}$$
 cot dip.  $\phi = \frac{T_1^2}{T^2}\phi$  cot  $v$ 

where  $\theta = \text{dip}$ . For one linear unit of scale and r units of distance to mirror the value of  $\phi = \frac{1}{2\rho}$ .

The dip is to be determined by means of the dip circle. For a particular scale value,  $T_1$  having been determined, we alter the position of the center of gravity by the adjusting screw, until by trial the desired value of T is produced. The scale value may also be ascertained by means of deflections, the magnet being first in a horizontal, next in a vertical position. (See p. 65 of 2d part of Bulletin, St. Petersburg, 1882.) \*

"The temperature compensation originally with the Brooke balancing magnetometer consisted of a glass thermometer tube filled with mercury. This has been removed, and a brass arm was substituted, as in the Adie instrument. The compensation operates as follows: Suppose the temperature is rising; the magnetic energy of the horizontal magnet will diminish, and gravity will consequently pull the south or unmarked end of the magnet down and thus elevate the marked end, but this is counteracted and the balance restored by the expansion of the brass arm which is directed to or on the same side as the marked end; the diminution of magnetic moment is thus counteracted by the increased leverage of the extended brass arm.

"Increasing scale readings should correspond to increasing vertical magnetic force or to a movement of the north cud of the magnet downward. The instrument is placed under cover of thick plate-glass.

"Referring to the diagram of the magnetic observatory containing the modified Brooke differential or variation instruments, it will be seen that the north seeking or marked ends of the magnets turn all to the inside or toward the telescope-pier. The directions in which the scale-numbers increase are also there indicated.

"Time being wanting for an accurate mechanical compensation of the force magnetometers, it is the intention that only the greater part of the change should be so compensated and corrections applied for the remainder. For this purpose thermometers are inserted, which are to be read in connection with the scales. The data for outstanding temperature correction will be had from the ordinary hourly observations."

The Point Barrow party was also put in possession of the resolutions adopted at the third session of the International Polar Conference, held at St. Petersburg, August, 1881. From this publication the following notes were taken:

"The differential magnetic observations for changes of declination, horizontal and vertical components of the earth's magnetic force, are to be made *hourly* and continuously, commencing as soon as possible on or after August 1, 1882, and closing as late as practicable before or on September 1, 1883.

"These hourly observations may be made either with reference to local time or with reference to any other meridian. [The full hours of local mean time are recommended, and the instruments are to be read in the order, bifilar 1½ minutes before and after, unifilar 1 minute before and 1 minute after, and balance magnetometer ½ minute before and ½ minute after each full hour.]

"Term-day observations.—Term-days are the 1st and 15th of cach month (excepting January 1, when January 2 will be taken). The differential instruments on term-days are observed every 5 minutes throughout the 24 hours, and strictly according to Göttingen mean civil time, beginning with 0 m (or midnight, Göttingen.) The three instruments will be read as rapidly as possible, one after another, in the order given above, the declinometer being read at the exact full 6fth minute.

"Additional observations to be made on term-days during one hour are specified below. Declina-

\*If  $\epsilon$  -rangle which the line joining the centers of gravity and of motion makes with the axis of the magnet, we have  $\tan \epsilon \tan \theta = \frac{T_1^{(i)}}{T_1^{(i)}}$ ; also  $\frac{\Gamma}{H} = \tan \theta$ , and since in our case  $\alpha \ge 90^\circ$ , formula (3) of p. 63 changes to  $\delta V = H \frac{T_1^{(i)}}{T_2^{(i)}} \psi_1$ , hence,  $\frac{\delta V}{T_1^{(i)}} = \frac{T_1^{(i)}}{T_1^{(i)}} \psi$  or  $\theta_2$ , as above.

tion observations will be made every 20 seconds, beginning with the full hour and minute of Göttingen mean civil time.

"If three observers are available, all three testringer's will be observed.

"Absolute magnetic measures of declination, dip, and intensity.—Observations are to be made as often as necessary to furnish the absolute values needed for the differential measures. |Unless some change is suspected in the latter, it will suffice to observe for absolute values the declination, the dip, and the horizontal intensity (oscillations and deflections) on the day before each term-day. Declination observations will then be made about 8 a. m. and 1 p. m., local time, and for these and the intermediate hours the corresponding readings of the scales of the differential and absolute instruments will be given. Observations for dip and intensity may be made at any convenient time of the day,—Sch.]

"Tests are to be made for possible local deflection before selecting the position for the absolute instruments.

"Scale values of differential instruments.—The unifilar or declinometer should have a sensitiveness such that 1 millimeter on the scale will correspond to a variation in declination (D) equal to V, hence  $\delta D = V$ . For the bifilar or horizontal force magnetometer at a place where the dip is  $\theta$ , 1 millimeter of its scale will be made to correspond to a variation of the horizontal component tH) of the magnetic force equal to 0.001  $\cos\theta$ , hence  $\delta H = .001\cos\theta$  expressed in the metric units of the force mm, mg,  $\kappa$ . For the vertical force or balance magnetometer, 1 millimeter of the scale will be made to correspond to a variation of the vertical component (V) of the force =0.001, hence  $\delta V = .001$  in the same units as above."\*

For absolute measures the Point Barrow party had Coast and Geodetic Survey magnetometer No. 11, and the Lady Franklin Bay party magnetometer No. 12, both new instruments, made by Fauth & Co., of Washington. Kew dip circle No. 23 was taken to the former place, and Kew dip circle No. 19 to the latter, both instruments the property of the Coast and Geodetic Survey. The magnetometers are described and figured (Plate No. 36) in Coast and Geodetic Report for 1881, Appendix No. 8. The Kew dip and intensity circles with needles 9 centimeters in length are well known.

#### GEOGRAPHICAL POSITION OF UGLAAMIE STATION, ALASKA.

The two United States Polar expeditions which had been organized under the orders of W. B. Hazen, brigadier and brevet major general, U. S. A., and Chief Signal Officer, left for their respective destinations early in the summer of 1881, the one for Alaska in command of P. H. Ray, lieutenant, U. S. A., the other for Lady Franklin Bay in command of A. W. Greely, lieutenant U. S. A.

"Supposing, for the sake of illustration, that at Point Barrow H .0.95 (in mm, mg, s, units) and  $\theta = 41\frac{1}{2}$ , then  $\cos \theta$  .4478 and  $\delta H \approx 0001478$  .  $\frac{1}{6766}$  hearly. From  $\cot z = \frac{\delta H}{H avc}$  we have  $\log \cot z = 9.72822$ , hence z = 61-52 and the whole angle to be turned off would be 90-4z: 151-52. For the vertical force instrument we have from V = H tan  $\theta$ ,  $V \approx 6.3565$ ; also, total force F = H see  $\theta = 6.4272$  and for  $\delta V = .001$  (metric units),  $\frac{\delta V}{V} = .0001573$ . The angular value of one division of each of the scales equals 1.

0 - 814 , then -61 52 and

ve have from 0001573 The Lieutenant Ray's party sailed from San Francisco in the Golden Fleece, July 18, and arrived off Ughamie, near Point Barrow, September 8. The meteorological and magnetic station was established near the small Esquimaux settlement of that name,\* about 17 kilometers or 10½ statute miles from Point Barrow and to the southward and westward of it, about 150 meters from the coast of the Arctic Ocean, and at an elevation of about 5 meters above its level.

The geographical position of the station, as derived from dead reckoning on board the Golden Fleece, is given by Lieutenant Ray t as follows: Latitude 71° 17′ 50″, longitude 156° 25′ 45″ west of Greenwich. The astronomical observations at Ughamie for position and direction of meridian were made by A. C. Dark, and are contained in Appendix I to this report. Observations found defective or unreliable from whatever cause have been omitted in this appendix. The latitude here adopted results from two sets of observations, one of a series of double altitudes of the sun on April 28, 1882, the other of two sets of single altitudes of the sun about upper and at lower culmination on June 24, 1882. The first value from sextant observations has been given the weight 4, and the second value from theodolite observations the weight 1: the resulting latitude becomes m. 71° 17'.7 with an estimated probable error of 4 0'.3 According to British Admiralty Chart 2164 the position of Ployer Point, where the English relief expedition under Commander R. Magnire, Royal Navy, was stationed in 1852, 1853 and 1854, is in latitude 149.21/25", and in longitude 156° 16′ 06′′ west of Greenwich. Following the trend of the coast being en the cemetery and summer camp down to Uglaamie and converting the linear measures of the chart into difference of latitude  $\Delta \varphi$  and difference of longitude  $\Delta \lambda$ , we find the latitude of e-glaamic station 71° 21′.1 -- 3′.5 = 71° 17′.9 and for the longitude of the station 156° 16.2° 4-2° 4 = 156° 44′.5 west of Greenwich. Since neither the first (nautical result) nor the last result (depending on estimated direction and distance) can compare in accuracy with the value deduced at the station, I shall adopt the value  $\varphi = 71^{\circ} 17'.7$ 

The longitude adopted results from a chronometric determination harde by the supply expedition in the summer of 1882 in the Leo, under the command of Lieutenant Powell, Signal Corps, U. S. A. The result as worked out by Mr.W. Upton, computer in the office of the Chief Signal Officer, is given in his report appended to "Signal Service Notes, No. V., Work of the Signal Service in the Arctic Regions, prepared under the direction of General Hazen, Washington, 1883." It depends on four chronometers, the sea-rates of which could be established from observations at San Francisco before and after the voyage, and at Plover Bay. East Siberia, during the voyage, though neither at Plover Bay nor at Uglaamie did the weather prove favorable. Mr. Upton's result is  $10^6$   $26^m$   $39^s \pm 10^s$ , or  $156^\circ$  39'  $45'' \pm 2'$  30''; it will be seen that this result is intermediate between tlet derived from dead reckoning on board the Golden Fleece and from the English determination of their station in 1853 to the southward and eastward of Barrow Point and referred to our station. Moreover we have two sets of lunar distances from the sun July 7, 1882, with the resulting longitade 10h 25m 57s, and a set of lunar distances from Jupiter as observed at Point Barrow and referred to Uglaamie by the addition of 1<sup>m</sup> 25\*, giving the result 10<sup>h</sup> 27<sup>m</sup> 14\*; the mean of these two astronomical determinations is 10<sup>h</sup> 26<sup>m</sup> 36°, which agrees so well with the above chronometric value, that I have adopted the latter, viz:

 $\lambda = 10^{h} 26^{m} 39^{s}$  or  $156^{\circ} 39' 45''$  west of Greenwich.

For the magnetic work we need the difference of longitude between Uglaamie and Göttingen, Germany; taking the latter place to be  $0^{10}$  39 $^{10}$  46°.2 cast of Greenwich, we have the required difference  $11^{10}$  06 $^{10}$  25 $^{25}$  +  $10^{10}$ , by which amount Göttingen is east of Uglaamie.

The magnetic work at Uglaamie, 1881, 1882, 1883.—The necessary buildings were erected without delay; October 3, 1881 the party was housed. October 17 the meteorological observations were commenced, the instruments were mounted in accordance with the plan furnished with the instructions, but it was not till the 1st of December that the magnetometers were adjusted and the regular hourly magnetic observations were recorded. Lacutemant Ray remarks:

<sup>\*\*</sup> Called Ootivakh on Ivan Petroff's map of Alaska, Tenth Census of the United States, Washington, 1882. The name of Kokmullit, given on this nap, is that of an Esquimaux settlement at Point Barrow. It is called Non-wook on the Admiralty Chart of 1853 (No. 2164.)

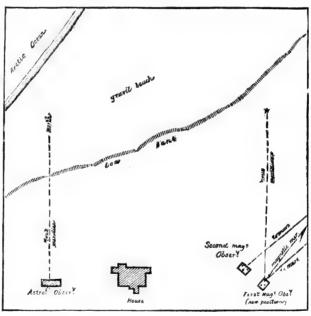

Report of Chief Signal Officer of September 15, 1881.

<sup>;</sup> In his report to the Chief Signal Officer, dated at Ughamie, Aug. 25, 1882.

"The three magnetic instruments were mounted on wooden piers, the season being too far advanced to place masonry. Posts 12 inches square were set into the frozen earth to a depth of 1 foot, and eemented into their place by pouring water around them and allowing it to freeze. The piers answered every purpose, were perfectly solid, and did not change their position in the slightest degree, and when the observatory was taken down this summer I found their earround their base unmelted. As soon as the weather was warm enough, brick piers capped with stone were placed, and the instruments are now all in position on permanent piers." This operation occasioned an interruption in the hourly observations from July 22 to July 30, 1882. This first series closed with September 9, 1882; it includes term-day observations, also hourly observations of dipping needle deflected by a constant weight as a substitute for a vertical force measure; these latter observations of relative total force, while of small value as differential measure, may nevertheless supply means for computing changes in the intensity which otherwise would have been wanting.

The supply party in the Leo arrived off Uglaamie Angust 20, 1882, with the Brooke magnetometers; they were mounted on brick piers, in a building especially erected for them, and their relative position was in strict conformity with the plan contained in the instructions. So long as thawing weather continued these piers lacked somewhat in stability, but the frost soon rendered them immovable. These instruments having been adjusted, the hourly series of observations commenced September 12, 1882, and were continued without interruption to August 27, 1883; the term-

U. S. Polar Station, Uglaamie, Alaska.

day observations and those for absolute measures were continued throughout the second year of the occupation of the place.

It has already been mentioned that in consequence of unfavorable conditions betwoen August 22 and August 29, 1883 (when the station was abandoned), no verification of the magnetic works could be made by Mr. R. A. Marr, but on the return voyage some magnetic observations were secured at Unalashka, and after the return of the instruments to Washington some additional verification work was done by Sergeant Maxfield in January and February, 1884.

The accompanying sketch shows the location of the magnetic observations and the position of the instruments.

The first position of the magnetic observatory was a little to the westward of the new position shown on the sketch; the change was made in July, 1882.

#### PART IL-ABSOLUTE MEASURES.

MONTHLY VALUES OF THE MAGNETIC DECLINATION, DIP, AND INTENSITY AT UGLAAME, DE-CEMBER, 1881, TO AUGUST, 1883.

The horizontal direction of the magnetic force at Ughaamie was determined by means of Fauth & Co.'s magnetometer, Coast and Geodetic Survey, No. 11, mounted on the northern pier of the magnetic observatory built soon after the arrival of the party. In July, 1882, it was shifted to a new position, where it remained to the close of the work. This instrument served both for the absolute as well as for the differential or variation measures; the latter observations, however, were discontinued or the arrival in the second year of the Brooke variation instruments. The instrument was not well adapted for differential work, as has been stated.

From returns brought home in the Leo, it was evident that the declinations were defective, for some reason not then apparent; also, that the magnet, which was a new one, had parted with much of its magnetism. It became desirable, therefore, practically to test the condition of the instrument for accurate work as soon as this could be done. It was returned to the office at Washington January 12, 1884, and after undergoing some trifling repairs, due to defective packing. Sergeant Maxifeld was directed to determine the declination with it at the magnetic observatory in this city,\* also to furnish some additional measures of the instrumental constants, those obtained by Sergeant Smith in June, 1881, not being deemed sufficient. These measures proved that the instrument was still in a satisfactory condition.

When the full returns came to hand it became evident that the discrepancies noticed in the monthly values of the declination were due to a want of attention to the suspension fiber. The plane of detorsion was apparently placed in the magnetic meridian in December, 1881, but no further test or adjustment was made till March, 1883. During this period the force of torsion had gradually increased (from unknown causes) and affected the declination to the amount of nearly 5½° in September, 1882. After this date this deflection remained perfectly steady, until removed in March, 1883.

For the first six months the monthly results refer to the mean declination of the day (from 24 hourly values), but after the arrival of the Brooke differential instruments the declinations were referred to the mean of the respective months through hourly corresponding readings of the Fauth & Co. magnetometer No. 11, and the Brooke declinometer. These corresponding readings generally extend over 6 hours on each day of observation.

The record and computation of the absolute measures are contained in accompanying Appendix No. 2. Placing little reliance on the determination in December, 1881, on account of a weak astronomical azimuth, and omitting for the present all results of 1882 and those for 1883, up to the middle of March, we have the following reliable values, which rest on a new astronomical azimuth, determined July 25, 1882, and which are roughly checked by a second measure, taken on the Brooke declination pier August 31, 1882, the same mark+ being used and all distances being known. The observations of July 31 are rejected, there being apparently an error of about 4½°:

<sup>&#</sup>x27;The observations made February 5 and 7, 1884, gave for the declination 3° 57',9 W. The same computed from annual observations made at Washington, D. C., since 1877, is 4° 00°,4 W.; difference, 2'.5. The measures for intensity were conally satisfactory.

t Distance magnetometer No. 11 to mark 900 feet, and to Brooke declinometer, 39.5 feet. First position of instrument November 21, 1881, azimuth of mark on house, 96° 13′ W. of N. from observation on Jupiter: second position of instrument, July 25, 1882, mark 46° 36′ E. of N. from observation of the sun.

New position of instrument and a new azimuth used here.
Thosion partly removed by observed at the torsion. After this date the magnet was suspended on a single fiber; it had previously been suspended on two fibers.

Toward the middle of August, 1882, the deflecting force of torsion had become constant and remained so till the middle of February the following year. For this period we have the following means and the corresponding monthly means of the readings and of the Brooke differential magnetometer: the mean correction to the absolute results is then found as shown below:

| Date                              | D <sub>1</sub>  | Brooke                             | A.H M M        | $D + \Delta r$ | Correction<br>for | Corrected        |  |

|                                   |                 |                                    |                | Меан           |                   |                  |  |

The two values within parentheses in column headed r are interpolated: Mean reading of declinometer for the last 5 months, 4764.2, and for the preceding 5 months, 4884.4, hence difference for 5 mor  $^{4}$ hs,  $12^{4}$ , 2, or monthly change, 2', 4, and the first interpolated value becomes  $4 \times 2.4 + 488.4 = 498.0$ The ofth column gives the computed declination corresponding to difference  $r_0 - r$ , or for the reading r, and the torsion correction is determined by the difference  $D = D_1$ . Our completed series, when compared with the preceding series (March to August, 1883), exhibits necessarily a trace of the comparatively rapid monthly decrease in the differential series between February, 1883 (mean 489.5) and May, 1883 (mean 476.1), but the magnitude of the errors of observation of the absolute measures forbids any attempt at correction of the differential series. Omitting the value for August, 1882, we finally have the table of absolute values, as follows:

Resulting monthly means of the magnetic declination at Uglaamic.

| 1862.            | 1 ( )    | 1863                |         |     |         |
|------------------|----------|---------------------|---------|-----|---------|

| November         | 43, 1    | May                 |         |     | 1216, 4 |
| December         | 34.2     | June                |         |     | 11.0    |
| 18863.           |          | duly                |         |     | 47.1    |
| January          | 42.1     | August              |         |     | 30.1    |
| February         | 51.5     | 74175,1171          |         |     |         |
|                  |          | For the epoch March | 1, 1883 | 15  | 37. 5   |

The value = 35° 27'.2 for the epoch March 1, 1883, is preferred to the value deduced above for the epoch June 1, 1883. The corresponding value of the Brooke declinometer reading is 484.7

Respecting the annual change of the declination due to the secular variation, we know from the general discussion of the secular variation, Appendix No. 12, Coast and Geodetic Survey Report for 1882, that the eastern declination in Alaska is now diminishing. The expression for the secular variation at the two stations nearest to Point Barrow, viz. Port Clarence, in  $\varphi = 65^{\circ}$  17' and  $\lambda = 166^\circ$  19' west of Greenwich, and Chamisso Island, in  $\varphi = 66^\circ$  13'.3 and  $\lambda = 161^\circ$  48'.7 west of Greenwich, give for the annual change in 1880 and 1885 the values + 10/3 and + 11/3 for Port Clarence, and + 10'.7 and + 12'.0 for Chamisso Island, and we have to expect a greater value at Point Barrow. Captain Maguire determined the declination at that place in 1853, and found = 40° 21', or, when reduced to Ughamje, about = 40° 06', which, compared with our value above, gives almost exactly a diminution of 44° between 1853 and 1883. It is known, from the other stations, that this declination has not passed through a maximum within the last thirty years, but has diminished gradually, with an accelerating rate. For uniform speed, the annual change would be + 10': it is, therefore, probably near + 15'. The absolute measures—September, 1882, to August, 1883—would give the value + 28/4, which is known to be greatly in excess, and if we fall back on the differential series, we obtain a value but a triffe less, and undoubtedly affected by torsion in the suspension skein of the declinometer, which was never re-examined after the first adjustment had been made. Omitting the readings between March and April, when the torsion was most pronounced, a discussion of the 5 monthly means, November, 1882, to February, 1883, inclusive, give a monthly change m = -0.97, and a discussion of the 4 monthly means for May, June, July, August, 1883, gives m = -1/.15, but if April be included m = -1/.92, mean = -1/.53; mean of first and last value -1/.25, hence annual change +15/.0, which is adopted as the most probable value.

#### ABSOLUTE MEASURES-RESULTS OF THE MAGNETIC DIP.

The observations were made with the Kew Dip Circle,\* L. Casella (London), No. 4370, or Coast and Geodetic Survey, No. 23.—It remained mounted on its pier in the small magnetic observatory during the stay at Uglaamie. The instrument left Washington June 23, 1881, and was returned January 12, 1884, only sustaining the breakage of one of the dipping needles. Test observations made by Sergeant Maxifeld at Washington in January and February, 1884, on four days, gave very satisfactory results. (See results for intensity.)

Observations were generally made on three days each month. The series commences with November 30, 1881, and ends with August 14, 1883. It does not appear that there is any appreciable difference in the results by needles 1 and 2; they are therefore combined indiscriminately. The following monthly means are made up from the individual results contained in Appendix No. 2, and they are here arranged with a view of deducing, if practicable, from the monthly values, taken at an interval of a year, a value for the annual change of the dip, independent of any annual variation.

Mean dip from twenty months of observation, 81° 23'.4, answering to the epoch October 1, 1882. Annual diminution of the dip, 1'.2

Applying the effect of the secular variation, or, more properly, of the annual change to the mean monthly values, i. e. to  $\frac{1}{2}$  ( $\theta_1 + \theta_{11}$ ) for the months from December to July, inclusive, and to  $\theta_1$  the correction—0'.6 for the months of August, September, October, and November, we obtain the following table of monthly dip values, all reduced to the same epoch, and which, therefore, should indicate any annual variation that may exist, unless in consequence of the smallness of such variation it be hidden by the observing errors:

#### 2. Table of mean monthly dips reduced to the same epoch (December, 1882).

If the results exhibited in the last column of the table can be trusted for such small differences from the mean (81°23'.1), they would indicate a slightly greater dip about the time of the vernal equinox and a slightly smaller dip about the time of the autumnal equinox.

The probable uncertainty of a monthly determination of the dip, *i.e.*, of any one of the values  $\theta_l$  or  $\theta_D$  is found to be  $\frac{2^{\ell} \cdot 5}{\sqrt{3}} = \pm 1'.4$  about.

Observations at Washington, D. C.; at Toronto, Canada; at Madison, Wis.; at Esquimault, British Columbia; at Sitka, Alaska, and at many intermediate places (see preface to "Diary of a magnetic survey of a portion of the Dominion of Canada," by General Sir J. H. Lefroy, London, 1883) show that the dip as well as the total intensity of the magnetic force are at the present time and have been for some years past slowly decreasing, and our result at Uglaamie is conformable with this general and extended action of the secular change. General Lefroy also states that at Fort Rae, Great Slave Lake, the present rate of the secular variation is -1/7 per annum, determined from comparisons of observations by Capt. H. P. Dawson, with an earlier deduction. Both at Washington and Toronto the dip reached a maximum in 1859, at which time it is nearly certain that the total force had been declining for some years. In 1853, Captain Magnire, R. N., found the dip at Plover Point, about 24 miles southeast of Barrow Point,  $81^\circ$  36' (Phil Trans. Roy. Soc'y, 1857, vol. 147, Part II, London, 1858), indicating an apparent diminution of 15 m 29 years, but if is highly probable that since Captain Magnire's occupation of this point the dip was on the increase for a few years before its present reversed motion commenced.

ARSOLUTE MEAST RES: HORIZONTAL COMPONENT, VERTICAL COMPONENT AND TOTAL MAGNETIC FORCE.

The observations for horizontal force were made with magnetometer Coast and Geodetic Survey No. 11, mounted on its pier in the small magnetic observatory; on its return to Washington in January, 1881, the glass tube was found broken; it was replaced by a spare tube, and after repairing some trilling damages, additional of servations were made here by Sergeant Maxifeld for a better determination of the instrumental constants.\* He also made the observations of deflections by gravity and by magnetism with the Laoyd needle of dipeircle No. 23, which were required to furnish the constant for converting relative total intensity into absolute measure.

Constants of magnetometer No. 11: Mass of ring 300.767 grains, outer diameter 3.779 cm., inner diameter 2.953 cm., thickness 0.529 cm., measured April 29, 1881, at 77° Fah., again from measures on April 30 at 73° Fah. outer diameter 1.4895 inches, inner diameter 1.460 inches, thickness 0.208 inches; the ring is of bronze. Moment of mass  $M_1$  at any temperature t (Fah.) in units of feet and grains=0.93070 [1+.00002 (t-75%)]. From observations of oscillations of long or intensity magnet  $L_{\rm H}$  with and without ring, by Sergeants Smith, in June, 1881, and Maxield, in January, 1881, we have at the temperature of 62 Fah.:

| 1 | Pate               | 31          |     |
|---|--------------------|-------------|-----|
|   | tam 1:<br>11<br>17 | 0<br>0<br>0 | 1 1 |
| í | January 28         | e 87, 15    | 3 ( |
| 1 | Wich Middle Can-   | M=0.87094   |     |

hence M for any temperature t (Fah.), M=0.87694 [1+,0000136 (t-62)]; length of collimator may not  $L_{11}$  2.48 inches, diameter 0.33 inch about; length of shorter magnet  $S_{11}$  2.04 inches, diameter 0.34 inch about. Scale of declination magnet  $L_{11}$ , 80 divisions; angular value of scale 37,69. The temperature coefficient determined from the monthly observations of the intensity at Ughamie was found to equal q=.00085, a value rather large and probably related to the rapid loss of magnetism of  $L_{01}$  when first magnetized; the magnetic momentum of this magnet changed from about 0.0693 (English units) in December, 1881, to 0.0671 in January, 1881.

From the monthly observations at Ughamie the following results were deduced

Table of resulting values for magnetic horizontal force (H) at Uglaamic, as determined by magnetometer

at Esquimault, to "Diary of a efroy, London, e present time is conformable states that at annum, deterluction. Both nearly certain 2. N., found the us. Roy. Soc'y, 9 years, but it on the increase

The following results were deduced from Sergeant–Maxfield's observations at Washington: A, anary 28, 4834, H = 6375 (English units); dip January 39, 31, 16bruary 1, 2, 1831,  $\theta$  = 50 - 35, 39, hence T = 43,185. These results over pare favorably with the values deduced (and referred to same time) from 18 years of annual determinations in the same place, viz. H = 4,378,  $\theta$  = 70 - 39,24, F = 43,218.

From evidence sit that to that given for the dip, but less conclusive, it is probable that H is on the increase, though the above amount appears far too large. In the discussion of Captain to nizes observations at Barrow Point in 1852-753-754, Sir Edward Sabine assumes H for that epoch to 1.15. This value when compared with the above would indicate an annual increase of about 40,005.

Second and independent determination of the horizontal force by means of the Kew Dip Carde, according to The replayed's method's of deflections by gravity and by magnetism in emperation with dip observables. This method has the great advantage of being independent on a compensation and of another of magnetisms of the needle, and applies well for stations in high

To an arguminating  $a^{*}=a^{*}$  . In a , a band and  $a^{*}=a$  , a aH a , the horizontal comparent so the force H there is a specificant a changes of or a discontinuous feed component Van Cawe total force F (resp. a)  $V_{t}(y,y,z)$  .  $F = \{H : H : t \in See \ | \ G \}$ 

Some that  $\sigma t = 41.2$  and  $\sigma H = 1.2$  are sized of V = 2.0 for V = 0.0 for the Euglish contrast Vwhere  $\operatorname{ith} \delta H = \operatorname{corps}_{\delta} \delta V$  and  $\delta P$  georges.

The topography of the accompanying map is compiled from surveys of 1853 (by C.49 %, Maguire, R. N.), of 1881 '83 (by Lieutenant Ray, U. S. A.); for the positions and names of the small lakes northwest of Ughanale I am indebted to Sergeant Murdoch; the two astrones and stations are haid down by their observed latitude and longitude. The d. tribution of the production of the PSSI is also with by two is agonic lines, the direction and distance of which are taken from reversible for 1883 is also with the United States (Coas) and Geodetic States (Coas) and Geo

thy Captall, unuses on the isstrong captall lact, and the captall captall lact, and detre show a line in a manufacture.

### PART III.—DIFFERENTIAL MEASURES.

HOURLY VARIATIONS OF THE DECLINATION, HORIZONTAL AND VERTICAL INTENSITIES, WITH BE MONTHLY TERM-DAY READINGS, AT UGLAAME, DECEMBER, 1881, TO AUGUST, 1883.

1. The observations of the first year of occupation consist of hourly readings of the Fauth & Co. magnetometer, Coast and Geodetic Survey No. 11; of the bifilar magnetometer, Coast and Geodetic Survey No. 2; and of Dip Circle, Coast and Geodetic Survey No. 23, comprising variations in the magnetic declination in the horizontal and in the total intensities between December, 1881, and September, 1882, together with term-day readings at the beginning and middle of each month, as agreed upon for the Polar stations. There were four observers, viz: Sergt. James Cassidy, Sergt. John Murdoch, Sergt. Middleton Smith, and A. C. Dark. They took regular turns, each observing four hours at a time. Fifteen readings were taken each hour, five for each instrument, viz, 6 minutes and 3 minutes before and after rad at the full hour, commencing with the declinometer and immediately followed by readings of the biblar and dip instruments. The temperature was noted. The presence of an aurora is indicated by an asterisk.

The instrumental outfit of the second year of occupation being far more complete than that of the first year, only so much of the record and discussion of the first year's work will be given here as seems desirable; further consideration will be given to this year's record after the presentation of the second year's work.

11. The observations of the second year of occupation consist of hourly readings of the Brooke magnetometers, comprising variations in the magnetic declination, in the horizontal intensity, and in the vertical intensity, between September, 1882, and August, 1883, together with term-day readings on the 1st and 15th of each month, as agreed upon for the Polar stations. The observations were made by six observers, viz: Sergeants Murdoch and Smith and Mr. Dark, as in the previous year, and Sergt. J. E. Maxfield, with Privates C. Ancor and J. Guzman. They took watches of four hours each in regular rotation. Six readings were taken every hour, viz: The horizontal force magnetometer was read 14 minutes before and again 14 minutes after the full hour, the declinometer was read 1 minute before and 1 minute after, and the vertical force magnetometer 4 minute before and 4 minute after the full hour. The temperature was noted by two thermometers suspended inside the cases or zinc covers of the horizontal force magnetometer and of the declinometer. Suitable centigrade thermometers had been ordered, but they were not received in time, and none was placed inside the case of the vertical force magnetometer. The temperature of this magnet can be inferred from the mean of the readings of the thermometers of the other instruments, which rarely deviated more than half a degree. The presence of an aurora is indicated by an asterisk.

#### ADJUSTMENT OF THE BROOKE DIFFERENTIAL MAGNETOMETERS.

The unifilar magnetometer.—The length of 1 division of the scale is 1 millimeter; the radius, mirror to scale, is 1.719 meter; hence the angular value of 1 division of the scale=1'.

 Observations for torsion coefficient, September 9, 1882, 1<sup>h</sup> p. m. When in the magnetic H. Ex. 44——59 meridian the plane of detorsion read 164° 30′, and by turning the torsion circle 90° first backward,• next forward, and again to the first position, we have the readings:

| Torsion circle.             | Scale r                | eadings.               | Mean.                     | Differences.                                     |  |  |  |  |
|-----------------------------|------------------------|------------------------|---------------------------|--|--|--|--|--|
| TOTALON CITCAG.             | Left.                  | Right.                 | mean.                     |  |  |  |  |  |
| 164° 30'<br>74 30<br>254 30 | d<br>530<br>456<br>684 | d<br>519<br>416<br>490 | 8 524.5<br>436.0<br>594.5 | d<br>88,5 for 90<br>155,5 for 180<br>88,5 for 90 |  |  |  |  |

Mean deflection  $a=83^{\circ}.1$  for  $\beta=90^{\circ}$ ; hence  $\frac{\hbar}{f}=\frac{83.1}{5316.9}$  0.01563, and the scale value  $\alpha=1^{\circ}.016$ 

The fixed mirror was set to show scale division 50 bisected, and at 0<sup>b</sup> 08<sup>m</sup> (September 10) a. m., Göttingen mean time, the magnetometer (movable mirror) was set to read 524.

- (2) On November 1, 4h 52m p. m., Göttingen time, both mirrors set to read 500.
- (3) The instrument was readjusted November 3, 6<sup>h</sup> 10<sup>m</sup> p. m. At 3<sup>h</sup> 47<sup>m</sup> p. m. the plane of detersion was found to read 51° 52°, when the following observations were made:

| Torsion                 | eirele.                     | Scale in; |                             | D  | ifferences.                            |
|-------------------------|-----------------------------|-----------|-----------------------------|----|--|
| 510<br>141<br>321<br>51 | 59'<br>52<br>52<br>52<br>52 | 1 3       | # 1<br>86<br>92<br>84<br>87 | 20 | 964 for 90°<br>18 for 180<br>13 for 90 |

Mean deflection  $a=104^\circ.3$  for  $\beta=90^\circ$ ; hence  $\frac{h}{f}=\frac{104.9}{5205.7}\pm0.01970$ , and the new scale value a=1/020

Fixed mirror reads 500, and the magnetometer (movable mirror) was set to 493 at 55 165 a.m., November 4, Göttingen time. Increasing scale divisions denote increasing easterly declination.

<sup>\*</sup> The circle is graduated from left to right.

## DIFFERENTIAL MAGNETIC OBSERVATIONS AT UGLAAMIE.

HOURLY READINGS OF THE BROOKE DECLINOMETER FROM SEPTEMBER 12, 1882, TO AUGUST 27, 1883,

Increasing scale numbers denote increasing easterly declination. Value of one division of scale between September 12, 1882, and November 3, hast observation, a = 10.016; from November 4 to close of series, a = 1.029. The average scale reading, 69.7, corresponds approximately to 35° 37°.2 E. declination. The presence of an autora is unificated by letters, those; (a) a true, list visible, (b) a feedle display, (c) a bright appearance, (e) a brilliant display. The two readings of the declinometer are given for each only new world as their mean. The two readings are placed opposite the brace in the first column, and their mean directly below. The extreme search divisions are 200 and 600.]

Hourly readings of the Brooke declinometer, Uglaamie, Alaska, September, 1882.

(Göttingen time.)

#### SOLAR DIURNAL VARIATION OF THE DECLINATION, INCLUSIVE OF DISTURBANCES.

The daily variation of the magnetic declination is found by subtracting each hourly mean from the respective daily mean, and is given in the following table for the whole year, as well as for the half years, i. e., with sun in north declination and sun in south declination:

| Göttingen<br>civil time. |      | oie civil<br>ne. | April to<br>September,<br>o north<br>declination. | October to<br>March,<br>(a) south<br>declination, | Year. | Göttingen<br>civil time. | Uglaamie<br>time. |         | April to<br>September,<br>(5) north<br>declination. | o south | Year.    |

Apparent diurnal range, 6 months, sun north of equator, 44'.3 Apparent diurnal range, 6 months, sun south of equator, 39'.9 Apparent diurnal range, year, 40'.1

The most pronounced feature of the diurnal variation is the morning extreme easterly deflection between 7 and 8 a. m. This is in perfect accord with the times of eastern elongation at stations in lower latitudes: thus at Sitka,\* 8h a. m.; at Madison, Wis., 81; at Toronto, 73; at Philadelphia, 73: and at Key West, 84. The afternoon westerly deflection, however, appears to be delayed when compared with stations to the south of Ughamie. We have a maximum about 5 p. m., and a second and greater maximum about midnight, undoubtedly produced by disturbances, as shown in the accompanying diagram. At Sitka the westerly elongation occurs about 34 p. m.; at Madison. 14; at Toronto, 03 p. m.; at Philadelphia, 14; and at Key West, 13. At Sitka there is no trace of the irregular western deflections recorded at Uglaamie between 8h p. m. and about 2h a. m., as shown by the table in the foot-note. If we now refer to the observations made at Point Barrow during 1852, 1853, and 1854 (Phil. Trans., vol. 147, 1857), we find 8 a. m. to be distinctly the hour of the maximum of the easterly disturbances, which thus re-enforce the regular solar-diurnal variation about this time and produce the great easterly deviation exhibited by the diagram. On the other hand, the waterly disturbances reach their maximum between the hours 11 p. m. midnight and 1 a.m., when they obliterate the regular solar-diurnal variation. Retaining the disturbances, the eastern maximum deflection is recorded between 7 and 8 a.m.; excluding the larger ones, it occurs near 7 a.m.; the western maximum, disturbances included, is recorded at 5 p.m. (with a second maximum between 10 and 11 p. m.), but excluding the larger ones, the elongation reverts

It is also a noteworthy fact that the diurnal variations seem to depend little on the season, the deviations from the annual course for the half year with sun north of the equator, and for the half year with sun south of the equator, being small.

# SEPARATION OF THE LARGER MAGNETIC VARIATIONS, OR SO-CALLED DISTURBANCES, AND THEIR DISCUSSION.

In the present state of our knowledge there appears to be no other means of recognizing socalled disturbances in a series of observations except by their magnitude; that is, for any one observation or reading taken at random it is impossible to say how much of the measured quantity is due to the regular daily variation, and how much to other variations following different laws. Having formed preliminarily for any one month hourly average or normal values, and compared each observation at any hour with the normal value at that hour, the series of differences so obtained will disclose the amount of the so-called disturbances; and a certain limiting value requires to be found which shall separate the apparently regular values from the supposed disturbed values; i. e., those following different laws from the others.

In the discussion of that large body of magnetic material which had accumulated mainly through the support of the British Government about the middle of the present century, General Sir Edward Sabine was guided in his selection of a limiting value simply by practical considerations or by experience, and the eminent success which he had fully justified his method; yet when a

Diurnal variation (inclusive of disturbances) of the declination observed at Sitka, Alaska, from ten years of observations.

 $[\Lambda + {
m sign}]$  indicates deflection of north end of needle to the west; a - sign the opposite direction.]

The  $j_0$  much to be regretted that the magnetic observations taken at Sitka, Alaska, between 1848 and 1864, have a ver been fully discussed. As it appeared to me highly desirable to compare the diurnal variation of the declination of the hourly readings from the broken and irregular excise extending from 1848 to 1862. (The material for this combination had been collected by Mr. M. Baker, of the Joast and Geodetic Survey, in March, 1882.)

e casterly deflection gation at stations in at Philadelphia, to be delayed when bout 5 p. m., and a urbances, as shown p. m.; at Madison, a there is no trace 1 about 2<sup>h</sup> a. m., as a at Point Barrow distinctly the hour solar-diurnal variadiagram. years of observations.

+ 1.4 + 0.8 number of simultaneous observations made at different stations, as in the case of the present polar researches, require strict intercomparability of results, a more definite proceeding appears desirable.

I had made use of Peirce's criterion for the rejection of doubtful observations,\* or, here more appropriately expressed, for the separation of observations deviating largely in amount by reason of their following different laws from those to which the ordinary observations are subject; and in using the criterion in such a case it was put forward only with a view of securing some definito rale uniformly applicable.

The criterion was first employed by me in the discussion of Dr. Kane's magnetic observations of 1853, 1854, 1855, at Van Rensselaer Harbor, North Greenland;† afterwards for Dr. Bache's magnetic observations of 1840 to 1845 at Philadelphia,‡ and for the United States Coast Survey magnetic series of 1860 to 1866 at Key West, Florida.§ In these applications, where no great precision is required, its method of application may be much simplified. Thus the mean deviation or the mean difference of any hourly value from its hourly normal may be found, without the trouble of forming squares, by the simple expression of  $\varepsilon=1.25\,\frac{|J|}{N-1}$ , and the limiting value given by the criterion will be =  $\pi$   $\varepsilon$ , the value of  $\pi$  being a tabular value for the case  $\mu=1$ , is readily had from Chauvenet's Table X. The limit so found will be the widest one that may be employed, but

from Chauvenet's Table X. The limit so found will be the widest one that may be employed, but in special applications it may require contraction, for the reason that the number of the largest disturbances is found to be insufficient for their successful discussion. Instead of using Peirce's criterion, we can, however, arrive at an equally satisfactory fixation of a limit by means of the expressions of either the probable or the mean error of an observation. We may define the widest limit as that deviation or difference from the mean which exceeds 3.5 times the probable variability or probable deviation of an observation. This limit corresponds to  $\frac{3.5}{1.483}$  or to 2.36 times the mean

deviation (as already used in connection with the criterion). Thus 24 times the mean deviation would be a superior limit, whereas Dr. Lloyd (1874) adopts for the discussion of the disturbances a limit of 14 times the exerage departure of a reading from its normal. By taking this lower limit we necessarily include a number of disturbances of lesser magnitude; but should the limit be drawn still closer there is danger of confusing the results with values following different laws from those which govern the larger disturbances. It would be most desirable to investigate the disturbances by a series of graduated limits and falling between these extremes. A limit somewhere between 2 and 14 times the mean deviation will probably be found most satisfactory. To find the mean deviation  $\varepsilon = 1.25 \frac{\Sigma}{n-1}$  say from an hourly series of observations extending over one year, the diar-

nal as well as the annual variations of the disturbances must be taken into account; and it will suffice to deduce 24 numerical values for  $\varepsilon$ , using for the first month the hours 0 and 12, for the second month the hours 1 and 13, for the third the hours 2 and 14, etc., and finally to take the average  $(\varepsilon)$  from the 24 individual values so obtained.

Discussing the hourly variations of the declination recorded in the second year at Uglaamie, where the horizontal component H=1.936 English units (=0.8927 Gaussian units, or 0.08927 dynes) for October, 1882, the value of  $\varepsilon$  equals 18'.4 nearly; hence limit by Peirce's criterion = 44', and the same limit for  $2\frac{1}{3}$  times  $\varepsilon$ ; for twice  $\varepsilon$  the limit is 37', and for  $1\frac{1}{2}$   $\varepsilon$  it is 28', which limits separate, respectively, 1 disturbed observation in 17 observations, 1 in 12, and 1 in 8. General Sabine's limit in the discussion of Captain Magnire's observations of 1852, 1853, and 1854 was 22'.87, and the number

<sup>\*</sup> United States Coast Survey Report for 1854, pp. 131 to 138; Gould's Astronomical Journal, No. 83, Cambridge, Mass., April 24, 1855. It is now most readily accessible in Chauvenet's Manual of Spherical and Practical Astronomy, Vol. II (first edition, Philadelphia, 1863).

<sup>§</sup> United States Coast Survey Report for 1874, Appendix No. 9.

Here, of course, the differences of the tabular hourly readings from their respective hourly normals do not, in any sense, represent errors, every one being as correct as any other; they are variations governed by unknown laws, probably of much complexity. The application of the formulae of the method of least squares to such phenomena is more or less precarious; the pure observing error may be regarded as insignificant.

H. Ex. 44----61

of disturbances separated was between  $\frac{1}{6}$  and  $\frac{1}{6}$  of the whole number; but it should be remarked here that at that time we were approaching an epoch of a sun-spot minimum, whereas at present we have just passed through a sun-spot maximum, during which the disturbances are greater.

It has been noticed that a limit adopted for a station in low magnetic latitude will not serve to deduce a limit for a station in high magnetic latitude when having regard only to the supposition that the limits are inversely proportional to the magnitude of the horizontal components of their respective magnetic intensities; the disturbances appear to increase in greater ratio as we approach the magnetic polar regions.\*

The further discussion of the differential observations must be deferred until a decision has been reached by the fourth international polar conference (which is to meet shortly at Vienna) respecting the limit of recognition of disturbances.

[April 5, 1884.]

#### THE BIFILAR MAGNETOMETER.

The length of 1 division of the scale is 1 millimeter, the radius mirror to scale is 1.719 meter, hence angular value of 1 division of scale = 1.

(1) Adjustment and determination of scale value, September 11, 1882, 1h p. m.

With plane of detorsion in the magnetic meridian the torsion circle read 54° 42′. It was then turned with the suspended weight 90°, and read 324° 42′, in which position the fixed as well as the movable mirrors were made to read 500 on the scale. The torsion weight was then removed and the magnet inserted and the torsion circle turned to read 248° 35′. The movable mirror was next brought to read 500, by means of the serew regulating the distance between the two suspension threads. The angle z=324°42′-248°35′=76°07′ was calculated to answer the desired value of one division of the scale to represent a variation of the horizontal force of .001 cos.  $\theta$ , expressed in metric units (millimeter, milligramme, s). By inadvertence a mistake was made by the observers in their calculation (in the value of H), so that the scale value neither for the horizontal nor for the vertical force corresponds to the value proposed by the President of the Polar Commission. This was not discovered by them until near the close of the observations, when they judged it best to adhere to the old value. The magnetometers were thus given a sensitiveness fully double of what was intended they should have. The consequence was that many of the largest disturbances in the horizontal and vertical components failed to be registered, the deflections falling beyond the range of the instruments.

We have the scale value k in parts of the horizontal force=cot. z times 1'=.00007190, and multiplying by H, or 1.939, the scale value becomes .0001394 English units.

(2) September 18, 1882, 2h a. m. to 3h15m a. m., Göttingen time, readjusted bifilar instrument.

Plane of detorsion read  $60^{\circ}$  41'; turned torsion circle to  $330^{\circ}$  41', and movable mirror made to read 50; magnet inserted and torsion circle turned to  $254^{\circ}$  34'; movable mirror brought to read 50 by means of the adjusting screw. The angle z equals  $76^{\circ}$  07'; hence k, or the scale value, remains as above. The apparent change in the plane of the detorsion of  $5^{\circ}$  59' is due to shifting of the instrument.

(3) November 6, 1882,  $10^{\rm h}$  p. m., to November 7,  $2^{\rm h}$   $31^{\rm m}$  a. m. Göttingen time; readjusted instrument.

With plane of detorsion in meridian torsion circle reads  $52^{\circ}$  46'; adjusted movable mirror to 50, when torsion circle reads  $322^{\circ}$  46'; suspended magnet and made torsion circle read  $247^{\circ}$  12'; brought movable mirror to 50 by means of adjusting screw,  $z=75^{\circ}$  34'; hence k=.00007487 parts of the horizontal force, and multiplying by H the scale value becomes .0001452 English units.

(4) February 27, 1883, 3h 05m a. m. to 6h 55m a. m. Göttingen time, readjusted instrument.

Plane of detorsion in magnetic meridian, torsion circle reads 52° 55'; movable and fixed mirrors adjusted to 50, with torsion circle 322° 35'; suspended magnet and turned circle to 247° 14' and brought movable mirror again to 50 by means of the adjusting screw,  $z = 75^{\circ}$  21'; hence k = .00007604 parts of the horizontal force, and the scale value .0001474 English units.

<sup>\*</sup>Thus with the Key West (H = 6.74) limit of 2'.6 the Uglaamie limit would be 9' about. With the Philadelphia (H = 4.17) limit of 3.6 the Uglaamie limit would be 8', about. With the Toronto (H = 3.53) limit of 5.0 the Uglaamie limit would be 9', about.

d be remarked reas at present re greater. will not serve he supposition onents of their

the Philadelphia 5.0 the Uglaamie (5) February 28, 1883, 1h 13m a. m. to 3h 37m a. m. Göttingen time, readjusted instrument.

Plane of detorsion in magnetic meridian 40° 22'; turned to 310° 22', with fixed and movable mirrors at 50; suspended magnet and turned to 235° 01', with movable mirror at 50, by means of the screw,  $z=75^{\circ}$  21'; hence scale value as in preceding case.

(6) At 6 p. m., March 23, Göttingen time, the suspended mirror touched fixed mirror owing to

stretching of threads; raised suspension at 6h 45m p. m.

(7) At 6h 45m a. m., March 25, Göttingen time, suspension further shortened; again at 7h 10m p. m., same day.

(8) At 3h a. m., April 21, Göttingen time, fixed mirror read 486; changed to 500 before taking the 3 a.m. observations.

Increasing scale readings denote increase of horizontal force.

### HOURLY READINGS OF THE BROOKE BIFILAR MAGNETOMETER, AT UGLAAMIE, ALASKA, TOGETHER

[Uncorrected for temperature. The hourly readings are placed opposite a Frace in first column and the corresponding temperature inonced presed off the scale at the negative end it is indicated by (-46-5), when beyond the positive end by (1040-3). In taking the monthly offside the scale. A parallel dash (\*) In the falle indicates time of readington cut of instrument or change in value of one division, 15 2°. It is found as follows: mean of 6 days less 4 four September \*\* ) 18, inclusive, \$27.6; mean of 6 days less 4 hour September is to

Value of one division of scale

Between September 11, 1882, and November 6, 1882.
Between November 7, 1882, and February 27, 1883.
Between February 27, 1883, to close of series.

The average scale reading 419 corresponds approximately to hor izontal intensity.

#### WITH THE CORRESPONDING TEMPERATURE (FAHR.), FROM SEPTEMBER 12, 1882, TO AUGUST 27, 1883.

ately below them. Increasing scale numbers denote increasing horizontal force. Extreme scale divisions, —40 and 1040; when the magnet means of the hourly readings, disturbances included, the respective extreme values were substituted in the place of the unknown position. To reduce readings of billiar to an approximately uniform series subtract 318 divisions from each reading from September 23, inclusive, 500-6; difference, 318 divisions. The bottom line of means of readings includes the correction of —318 divisions.

### ometer at Uglaamie, Alaska, August, 1883.

was found as follows. Mean of 7 days, August 1 to 7 inclusive, 455 9, mean, August ≥ to 14, inclusive, 651 9, difference, 127 9.]
part of the borizontal force.]

Monthly means: Temperature, 459.5; readings, 501.2

ke bifilar magnet

347 - 466 - 147 - 156 - 147 - 15

The monthly means of the bifilar readings appear quite irregular, produced by large disturbances and by change in adjustment. The latter became necessary in consequence of the effect of temperature and moisture on the suspension. During the winter the observatory became thickly coated with ice on its sides and roof, which during thawing weather kept the interior atmosphere in a state of extreme moisture. The observed variations in the length of the suspension fibers and in the torsion of the two declination instruments may be thus accounted for, and the greater or less stiffness of the fibers was probably occasioned by moisture deposited upon it freezing and thawing alternately. The effects on the readings of changes of temperature and gradual loss of magnetism\* of the magnet or of such secular change are small compared with the above irregularities from other causes. It would seem desirable to use metallic suspension in the place of silk.

The September mean (619.5) was corrected to 519.1 by application of a rough correction of —318 divisions to the readings of the first six days, found by comparison with the mean of the succeeding six days.

In August, 1883, the mean reading was higher (639.7) than at any other time, and it was evident that the adjustment of the instrument had from some unknown cause been disturbed. One of the observers (Mr. Maxfield) states that when he took down the instrument on the 27th he found that the adjusting screw which holds the thread and determines the distance between the threads worked rather loosely in its bearings, whereas it was very fight when the instrument was first set up. It is difficult to fix upon a particular time when the rapid increase in the readings commenced, but it was most probably between August 7 and 8, and lasted for two or three days before the instrument settled again to a fixed condition. A slow, progressive motion is apparent from the last two days of July. For our present purpose the matter is of little importance, since we shall deal strictly in a differential way, only aiming at roughly comparable absolute readings. In order to reduce the monthly readings during August roughly to a uniform scale a correction of —187.0 divisions was applied.

Preapitulation of monthly mean values (inclusive of disturbances and uncorrected for changes of temperature and variations in scale values) of the hourly readings of the Brooke bifilar magnetometer at Ugacomic, Alaska, 1882–83.

### TEMPERATURE COEFFICIENT.

There were no special observations made to ascertain the effect of changes of temperature on the magnetic moment of the bifilar magnet; the instrument was mechanically compensated as near as could be judged; we have, therefore, to determine the outstanding effect by means of the

temperature on censated as near y means of the

### SOLAR-DIURNAL VARIATIONS OF THE MAGNETIC HORIZONTAL FORCE

Observed at Uglaamie, Alaska.

(Disturbances included)

Erdl curre——mean of the year, Sign, 1882, to Aug, 1883, incl.
Broken ———nean of 6 months, san in north declination.
Dated———mean of 6 months, san in south lexinarias.

ordinary hourly readings. During 1882, one lamp was continually burning in the observatory, but early next year three lamps were kept burning, the supply of oil in store being greater than was at first supposed. The annual average temperature in the observatory, as shown by a Fahrenheit thermometer inside the zinc cover of the bifilar, was  $\pm 19^\circ.0$  or  $\pm 7^\circ.22$  C.

In consequence of the irregularities in the state of the instrument as shown by the monthly mean readings, the only available method for deducing the temperature coefficient q appeared to be that of selecting a number of consecutive and undisturbed days at times when the temperature was rapidly changing, and find for each case the apparent change of the daily means in scale divisions corresponding to a change of  $1^\circ$  in temperature. The following values were thus found:

| Date.                             | Change of the daily means. | Corresponding<br>change<br>in temperature. | Change for<br>1º Fahrenheit |
|-----------------------------------|----------------------------|--|-----------------------------|

It is proposed to adopt provisionally the mean value  $-2.2\pm0.8$  which is equivalent to a decrease of 0.000165 part of the horizontal force for an increase of temperature of 1° Fah. or q=0.000165

In the following table the values in columns 3, 4, 5 are uncorrected for changes of temperature, the next three columns show the temperature differences for which corrections were required, and the last three columns give the diurnal variations thus corrected. The values are laid down on the accompanying diagram.

Solar-diurnal variation of the horizontal force, inclusive of distur' ances, and expressed in parts of the force, at Uglaamie, 1882-'83.

|  |  |

At Uglaamie the daily maximum value of the horizontal force occurs between the hours 5 and 7 p. m., and the daily minimum about 7 a. m.; there is also a very slight indication of a secondary disturbance in the regular progression between 3 and 5 a. m. corresponding to a second-

ary maximum about 6 a. m. as exhibited at Toronto, and more strongly at Philadelphia at  $5^\circ_1$  a. m. where it constitutes the principal maximum, the secondary occurring at 4 p. m. The maximum at Toronto takes place between 4 and 5 p. m. and the minimum about 10 a. m.

The diurnal inequality in the whole deflecting force acting in the horizontal plane may be exhibited graphically both in direction and magnitude as in the annexed diagram.

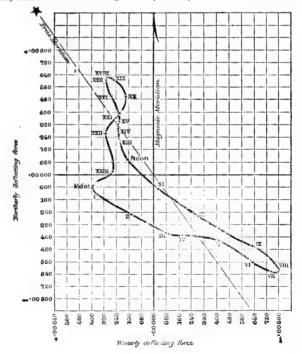

The origin of the co-ordinates represents the normal declination and horizontal force, and any line drawn from it to any part of the curve will represent in direction and magnitude (according to scale of diagram) the deflecting force acting at the time as marked against that point. If for any time the angle  $\psi$  equals the westerly deflection of the horizontal needle the deflecting force producing the same is  $H\sin\psi$ , and when expressed in parts of the horizontal force simply  $\sin\psi$ . A deflec-

tion of  $\psi$  minutes corresponds to  $\frac{\psi}{3437.7}$  or 0.000291  $\psi$ , parts nearly. The table of the solar-diur-

nal variation of the declination contains the values of  $\psi$  for every hour of the day, and the corresponding change in the force at right angles thereto is contained in the preceding table of the variations of the horizontal force; these two components, the westerly and northerly, appear combined in the diagram. It will be seen that the disturbing forces act more energetically in a plane approaching closer to the true than to the magnetic meridian, and that the usual character of the representation is changed by their action, that half of the curve containing the hours 21 (9 p. m.) to  $2\frac{1}{2}$ a.m. being thrown far to the westward, forming a loop, and beyond the branch containing noon; on the other hand, the great extension of the deflecting force between 7 and 8 a.m. is wholly due to the great activity of the easterly disturbances about these hours. This will become clear when the disturbances have been separated from the normal deflecting forces, and a diagram for the latter alone is presented.

DIURNAL VARIATION IN THE WHOLE DEFLECTING FORCE ACTING IN THE HORIZONTAL PLANE.

[The intensity of the total horizontal deflecting force is expressed in parts of H and all its disturbances are included.]

#### THE VERTICAL MAGNETOMETER.

The length of 1 division of the scale is 1<sup>mm</sup>, the radius, mirror to scale, is 1.719<sup>m</sup>, hence angular value of 1 division of scale = 1'. In consequence of the great sensitiveness given to the instrument, which was nearly double what it was intended it should have a few of the largest disturbances were beyond the range of the instrument during November, and thus failed to be recorded.

(1) Adjustment and determination of scale value September 9, 1882, noon. The knife-edge was brought into the magnetic meridian on the leveled agate supports; the magnet was balanced at 11<sup>h</sup> 22<sup>m</sup> p. m., Göttingen time; the fixed and movable mirrors were made to read 500.

Observations for time of one oscillation of magnet and appendages.

(3) Balance magnetometer adjusted November 14, 1882 (7 p. m. Göttingen time), so as to oscillate in 9\*,060 and to read 500 at  $10^{\rm h}$  05m p. m. (Göttingen time). This value for T was derived from 20 oscillations; no particulars are recorded. No observations of oscillations with magnet suspended. With  $T_1 = 18*,002$  and T = 9\*,060 we have scale value in parts of the vertical force 0.0001739, which is equal to 0.002223 English unit.

(4) Readjustment of balance magnetometer March 4, 1883. Instrument leveled, with supporting H. Ex. 44——65

edge in magnetic prime vertical (7 a. m. Göttingen time); magnet balanced by means of weights, and both mirrors brought to scale 50 (8 a. m. Göttingen time); magnet brought to oscillate in  $11^{\circ}.850$  by means of adjusting weight on upright stem ( $8\frac{1}{2}$  a. m. Göttingen time).

| 10 oscillations were performed* in.<br>10 oscillations were performed in   | 1    | 58.<br>58.<br>58. |
|--|------|-------------------|
| Hence $T=115.850$ With $T_1=185.002$ and $T=115.850$ we have value of one of scale in parts of the vertical force 0.0001017, which camps 0.001300 English. | divi | sio               |

\* By Chronometer Bond 188.

- (5) March 29, 1883, about 4 a. m. (Göttingen time) magnet removed, cleaned of slight frost that had collected on it, and replaced between 4 and 5 p. m.
- (6) April 15, 1883, magnet raised from support and lowered between  $6^{\rm h}$  55m and  $7^{\rm h}$  00m p. m. (Göttingen time).
- (7) Readjustment of the balance magnetometer April 27, 1883. Instrument leveled. Supporting edge in magnetic meridian for oscillations in horizontal plane 2<sup>h</sup> 12<sup>m</sup> a. m. (Göttingen time). Between 4<sup>h</sup> 10<sup>m</sup> and 5<sup>h</sup> 40<sup>m</sup> a. m. adjusted fixed and movable mirrors to scale division 50.

|                         |  | I                                     |   | 1                                     | 455               |

Time of one oscillation 65.974 - 455 + 4 = 1135.8; hence  $T_1 = 185.295$ 

Hence scale value for the time preceding April 27, using  $T=7^{\circ}.816$ , one division=0.0002413 part of the vertical force, or 0.003086 English unit, and after April 27 using  $T=6^{\circ}.974$ , one division=0.0003031 part of the force, or 0.003876 English unit.

- (8) May 3, 1883, magnet of balance magnetometer raised on support and lowered between 11 and 12 p. m. (Göttingen time). Found time of one oscillation in the vertical plane= $8^{\circ}$ .750; hence with  $T_1 = 18^{\circ}$ .295, one division of the scale=0.0001926 part of the vertical force, or 0.002462 English unit.
- (9) May 21, 1883. At 3 a. m. Göttingen time magnet fell off support; replaced and time of one oscillation determined 84,700; hence one division of scale=0,0001948 part of the vertical force, or 0.002490 English unit.

To reduce readings to an approximately uniform series increase each reading by 40.7 \(\cdot \) 65.0 \(=\) 105.7 divisions; it is found as follows:
Mean of 10 days, September 24 to October 3, inclusive, 444.1; mean of 10 days, October 4 to 13, inclusive, 454.8; difference, 40.7 For origin of number 65.0 see note to next month. One division of scale \(=\).000803 part of the vertical force. Monthly means: Temperature, 35\(^{\cdot 1}\)1; magnitude and other contents of the content of t

Hourly readings of the Brooke balance magnetometer at Uylaamie, Alaska, October, 1882.

To reduce readings to an approximately uniform series increase each reading of the 1st, 2d, and 3d by 105.7, and all remaining readings by 65.0 divisions. We have mean of 8 days, October 27 to November 3, inclusive, 451.3, and mean, of 8 days, November 5 to 12, inclusive, 5f.6.3; difference, 65.0 dno division of scale -, 0060803 part of the vertical force. Monthly means: Temperature, 189.4; magnetemeter, 451.1; reduced mean, 520.0

Hourly readings of the Brooke balance magnetometer, Uylaamic, Alaska, November, 1882.

To reduce readings to an approximately uniform system increase the readings of November 1, 2, and 3 by 65.0 divisions as explained in note to preceding month. Scale value to the first 3 days, account 3 for the next 11 days to November 14, 26 (c) cost6, for removed of month controls, average for month account of the vertical force. Monthly means: Temperature, 25.7; magic former, 54.2, where forces 1, 546.2, which is a control of the vertical force.

ber, 1882.

l remaining readings ser 5 to 12, inclusive, 8-, 4; magnetemeter,

Hourly readings of the Brooke balance magnetometer, Uglaas.ie, Alaska, December, 1882.

One division of scale = .00%1739 part of the vertical force. Monthly means: Temperature, 3%,7; magnetometer, 504.3

Hourly readings of the Brooke balance magnetometer at Uglaamie, Alaska, March, 1883.

ry, 1883.

To reduce readings to an approximately uniform series increase each reading between March 29, 45, and close of the month by 46.0, distincts, 450.1; mean 10 days, March 30 to April 8, inclusive, 499.1; mean 10 days, March 30 to April 8, inclusive, 439 4, difference, 40.9 Monthly means: Temperature, 1.5; reagnetometer, 56.3; reduced mean, 599.2.

\*March 29, about 4a, m, Gott, time, magnets cleaned of slight frost that had collected.

† Scale value up to March 4, 85, 2017.9; after the date, 360.0101; average for month, 300.087 part of the vert, latter.

H. Ex. 44----66

Hourly readings of the Brooke balance magnetometer at Uglaamie, Alaska, April, 1883.

Scal value of one division up to April 15, 0001017; between April 15 and 27, 0002413, after April 27, 65, 0003031; average for month, 0001814 part of the vert, force. To reduce readings to an approximate uniform series apply the corrections indicated in last column. We have means of 10 days April 27 to 26, inclusive, 460.1; mean of 10 days. April 28 to May 7, inclusive, 52; 2, difference 62; 1. Monthly means: Temperature, 12.15; magnetometer, 468.7; reduced mean 51; 3.

Hourly readings of the Brooke balance magnetometer, Uglaamie, Alaska, May, 1883.

1883.

15 225 236 Carte

for month, .0001844 L. We have means ans Temperature.

#### TEMPERATURE COEFFICIENT.

There were no special observations made to determine the effect of change of temperature on the magnetic moment of the balance magnet. The instrument was mechanically compensated as near as could be judged, and it only remains to determine the outstanding effect by means of the ordinary readings. There was no thermometer in the case of the balance magnetometer, but the same temperature record as was given for the bifilar magnetometer answers, since the readings of the two thermometers—one with the unifilar, the other with the bifilar—rarely differ more than half a degree and less than 0°.1 Fahr., in the monthly means. Applying the same process as in the case of the bifilar, we find—

It is proposed to adopt for the present value the value— $0^{4}.7\pm0.2$ , which is equivalent to a decrease of  $0.7\times.0001584$  (0.7 time the average value for 1 division) or .000111 part of the vertical force for an increase of temperature of 1° Faur.

Solar-diurnal variation of the vertical force, inclusive of disturbances, and expressed in parts of the force; Uglaumie, 1882-'83.

The numbers contained in the last three columns of this table were plotted on the accompanying diagram, which shows the vertical force to be in excess of its average value in the (local) morning hours maximum about 6 a. m., and in deficiency in the (local) afternoon hours minimum about 9 p. m. Compared with the variation of the vertical force at more southern stations, there appears to be a complete inversion of the hours of greater and of less intensity, which may be due to the action of disturbances; or, if regular, it may be somehow connected with the circumstance that Ughaumie is near the central zone of maximum auroral display, and a little to the north of it. We note the apparent greater range of the diurnal variation in the half year including the winter than in the other six months, which is also an anomalous phenomenon.

The breakage of the magnetic and electric equilibrium in this auroral zone, resulting in an outburst of disturbances, probably occurs more frequently in this beit than outside of it, and possibly sudden changes of temperature may be favorable circumstances of disruption. The belt of maximum auroral development seems to be subject to fluctuations in position, and in studying the supposed connection of auroras with terrestrial magnetism, attention should be directed to the direction in which the aurora appears at a station, i.e., at Ughamie, whether to the south or to the north of the zenith.

The increased dip and total intensity in the Uglaamie morning hours, as contrasted with the diminished dip and intensity of the total force in the afternoon, is corroborated by the observations made in the first year by means of the dip circle and deflecting weight.

SOLAR DICRNAL VARIATION OF THE MAGNETIC VERTICAL FORCE

Solar diurnal variations in the magnetic dip and in the total magnetic intensity.

These variations are readily obtained from the variations in the horizontal and in the vertical components of the force; if F = total force, H and V its horizontal and vertical components, then

on the accome in the (local) ours minimum stations, there ch may be due e circumstance he north of it, ing the winter

esulting in an of it, and pos. The belt of a studying the cted to the diouth or to the

sted with the observations

the vertical

onents, then

from the fundamental relations  $H=F\cos\theta$  and  $V=F\sin\theta$  we find by differentiation and elimination, the variation in the dip  $\Delta\theta$  and the variation in the total force (in parts of the force)  $\frac{\Delta F}{F}$ , viz:

Solar-diurnal variations in the magnetic dip and in the total magnetic intensity, inclusive of disturbances; annual mean values 1882-283.

In presenting the foregoing results of the three variation instruments I had two objects in view, viz, to be in a position to form a close estimate of the character and value of the whole series of observations preparatory to their full analysis and discussion, and, secondly, to give at once, but preliminarily, such leading results as could be deduced without waiting for the publication of the results of the conference for the uniform treatment of the magnetic work at the international Polar stations. What has been presented will, in general, enable the reader to form a judgment of the magnetic outfit of the Ughamie station, and of the value of the work done.

As has been already pointed out, there were no well-adapted magnetic variation instruments available in the first year; the range of the collimator scale was very limited, and the declinometer had frequently to be turned in azimuth in order to secure readings on days of disturbance; besides, the great changes in the torsion of the suspension renders it impossible to produce a uniform series at the respect to a fixed direction. The record of the biflar magnetometer has not yet been sufficiently examined to form an opinion as to its value, and at present I am still waiting for notes bearing on the edjustment and scale value of the instrument.\* There was then no vertical force magnetometer, but hourly observations were made with a dipping needle deflected by a constant weight; corresponding values for the true dip or deflections by the same needle were only made on two or three days each month, so that the value of this series, as a differential measure of the total force, may be regarded as small. It has, however, enabled me independently to verify the fact brought out by the balance magnetometer of the greater total intensity during the morning than in the afternoon hours. There is no record of the effect of temperature changes on the angle of deflection of the loaded needle.

In the year 1881-'82 there were but few stations with which to compare results, and to publish the above-mentioned records in extenso would seem to me an expenditure of time and labor hardly to be recommended, and probably not warranted by the meager results the series may be capable of yielding. If this early record is to be published at all I would propose to set down the mean of the 10 readings (5 with scale extreme left and 5 with scale extreme right) for each instrument, viz. the declinometer and bifilar, and the mean of the 10 readings of the dipping needle (5 for south and 5 for north end); for each observing hour and during term days it would suffice to give only the mean of the two extreme scale readings. But on these and other points the result of the deliberations at Vienna may be awaited.

I conclude this report with a table of frequency of the aurora as seen and recorded in connection with the magnetic work at Ughamie.

<sup>&</sup>quot;No further information could be obtained. May, 177 a

Table of frequency of the aurora as observed at Uglaamie, Alaska, between October, 1881, and August, 1883.

{The hours are local mean time hours at Ughamie, and the numbers indicate the number of days in each month when autoris were seen at each of the hours indicated: Observations began October 17, 1881; end, August 27, 1883. The presence or absence of an aurors was noted a few minutes before each full hour.}

The total number of days when auroras were visible in the first  $10\frac{1}{2}$  months (1881-'82), was 145, hence the average duration,  $5\frac{1}{2}$  hours nearly: total number of days when auroras were seen in the year ending August, 1883, was 169, hence the average duration,  $7\frac{1}{4}$  hours nearly.

In the tabulation and preparation of the manuscript record for the printer I had the assistance of Sergeant J. E. Maxfield and Private G. W. Knopf, who performed their task with much zeal and commendable industry; they have also prepared a complete duplicate of the records of the report.

#### PART IV.—SEMI-MONTHLY TERM-DAYAND TERM-HOUROBSERVATIONS.

OBSERVATIONS OF THE VARIATION IN DECLINATION, IN HORIZONTAL AND IN VERTICAL FORCE, READINGS OF THE DECLINOMETER ON TERM DAYS AT UGLAAMIE, ALASKA, SEPTEMBER 15, 1882, TO AUGUST 15, 1883.

[For scale values and other information see preceding part, III. Göttingen time is employed.]

Term-day readings of the Brooke declinometer, September 15, 1882.
